

# A METHODOLOGY FOR *THE IMAGE OF THE CITY*

Please place a checkmark (✓) to indicate within a pair which element is more important or dominant than the other, and indicate the degree of importance. For example, in a comparison of the pair, paths-edges:

		Equally Important	Moderately More Important	Strongly More Important	Very Strongly More Important	Extremely More Important
<div style="display: flex; align-items: center;"> <div style="width: 20px; border-bottom: 3px double black; margin-right: 5px;"></div> <div style="margin-right: 10px;">Paths</div> </div> <div style="text-align: center; margin: 2px 0;">or</div> <div style="display: flex; align-items: center;"> <div style="width: 20px; background-color: black; height: 10px; margin-right: 5px;"></div> <div style="margin-right: 10px;">Edges</div> </div>	<div style="display: flex; align-items: center;"> <div style="width: 20px; border-bottom: 3px double black; margin-right: 5px;"></div> <div style="margin-right: 10px;">Paths</div> </div> <div style="text-align: center; margin: 2px 0;">or</div> <div style="display: flex; align-items: center;"> <div style="width: 20px; background-color: black; height: 10px; margin-right: 5px;"></div> <div style="margin-right: 10px;">Edges</div> </div>	_____	_____	_____	_____	_____
	✓			✓		

This example indicates that paths are strongly more important than edges in an assessment of their imageability.

Comments: Rationale for this assessment is given with reference to the characteristics of paths or edges as observed (seen) in the field (survey).

Please note the slots provided between the five point scale of importance so that the intermediate values between two adjacent judgments can be indicated also.

For example, in a comparison of the pair, paths-nodes:

		Equally Important	Moderately More Important	Strongly More Important	Very Strongly More Important	Extremely More Important
<div style="display: flex; align-items: center;"> <div style="width: 20px; border-bottom: 3px double black; margin-right: 5px;"></div> <div style="margin-right: 10px;">Paths</div> </div> <div style="text-align: center; margin: 2px 0;">or</div> <div style="display: flex; align-items: center;"> <div style="width: 20px; background-color: black; border-radius: 50%; margin-right: 5px;"></div> <div style="margin-right: 10px;">Nodes</div> </div>	<div style="display: flex; align-items: center;"> <div style="width: 20px; border-bottom: 3px double black; margin-right: 5px;"></div> <div style="margin-right: 10px;">Paths</div> </div> <div style="text-align: center; margin: 2px 0;">or</div> <div style="display: flex; align-items: center;"> <div style="width: 20px; background-color: black; border-radius: 50%; margin-right: 5px;"></div> <div style="margin-right: 10px;">Nodes</div> </div>	_____	_____	_____	_____	_____
	✓		✓			

In this comparison, nodes are given more importance than paths (note the location of the checkmark), and the scale of relative importance reflects a 'compromise', checkmarked in a slot between 'moderately more important' and 'strongly more important'.

# FUZZINESS IN GEOGRAPHIC INFORMATION SYSTEMS: CONTRIBUTIONS FROM THE ANALYTIC HIERARCHY PROCESS

**Boolean Probability Logic**

An ordinary set defines crisp or exact boundary to include or exclude an element in the set.

An element is either included or excluded in a set.

Does not permit partial membership of an element in a set.

Membership functional values are restricted to two points (0, if element not in the set, 1 if element in the set):  
 $\{\mu_s(x) = 0, \text{ if element } x \text{ is not in set } S\}$   
 $\{\mu_s(x) = 1, \text{ if element } x \text{ is in set } S\}$ .

**Fuzzy Set Possibility Logic**

A fuzzy set allows flexibility in defining variable boundary thresholds to a set.

The inclusion of an element in a fuzzy set is a matter of degree.

Permits partial membership of an element in a fuzzy set.

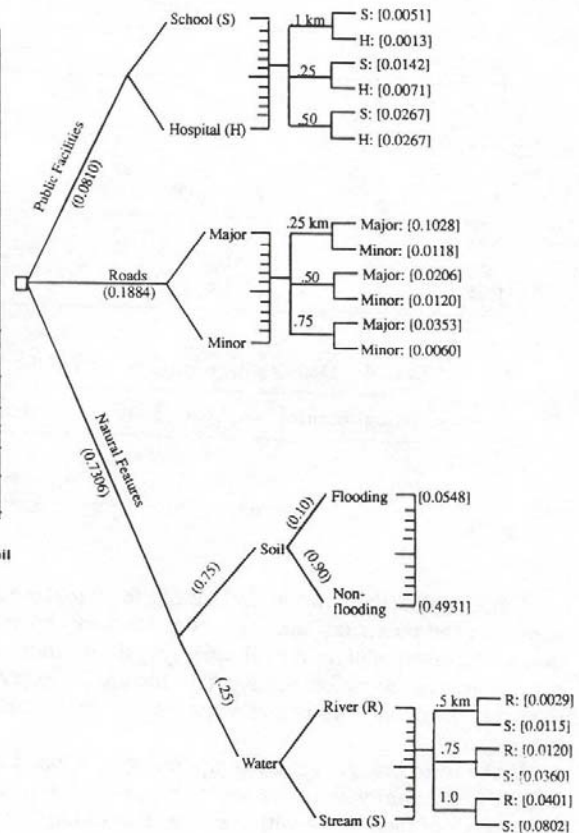

Membership functional values take the range of values between and including 0 and 1:  
 $0 \leq \mu_s(x) \leq 1$ .

**Table 5.** An assessment of transit-oriented development (TOD) and traditional neighborhood development (TND) by bid rent theory (BRT).

BRT	TOD	TND
Accessibility is a principle determinant of urban form	●	●
Accessibility is maximized at the town center, with availability of transportation networks	●	●
Market potential (access to producers and consumers) is optimum at the center	●	○
Trips are uniformly priced, homogeneous landscape, free market economy, profit maximization	●	●
Residential and industrial uses reflect the accessibility of the center, traded off for the lower rental at the periphery	○	○
Concentric pattern of land uses	●	●
Retail activities at the center, housing at the periphery	●	●

Note: ● strong relationship; ● moderate; ○ weak relationship.

**Figure 5.** (a) The 'concentric' pattern of retail at the core, and residential at the periphery in transit-oriented development (TOD) (source: adapted from Calthorpe, 1993); (b) a similar pattern in Seaside (source: adapted from Katz, 1994); and (c) the concentric zone pattern from bid rent theory.

## CRITICAL REALISM, AND URBAN AND REGIONAL STUDIES

**Table 1.** Critical realism: what can be investigated or known to exist (ontology)?

	Domain		
	real	actual	empirical
Mechanisms	*		
Events	*	*	
Experiences	*	*	*

\* Areas of investigation (Bhaskar, 1975)

Some properties of critical realism (see also Bhaskar, 1989; Johnston, 1989)

- (1) Bounded rationality. Knowledge is incomplete or partial owing to the complexity of social phenomena with interrelating parts.
- (2) Contingency, variability, and causality. Circumstances and situations vary in space and time. Therefore the particular circumstances and conditions under which the causal power(s) of universal mechanisms (such as capitalism) cease in their effect must be discerned.
- (3) Theory and experimentation. Knowledge of complex social phenomena is not gained by observation alone. A theory must accompany any empirical experimentation.
- (4) Predictability and explanation. Prediction demands intensive and extensive knowledge of likely combinations of mechanisms and their linked outcomes (events). Prediction is difficult; certain features of social systems cannot be subjected to controlled experimentation, or 'randomization'. However, 'conditional' prediction can be provided as explanation of 'possibility' of outcomes. Explanation is contingent upon the environment of experimentation.
- (5) Critical inquiry. Popular or 'nominal' definition or description of a problem need not be taken for granted. Critical assessment is needed to reveal assumptions otherwise concealed in common conceptions.
