## Spheromak temperature limits are between those for tokamaks and FRCs

(T. Rognien)

Spheromak edge plasma,  $R_h = 0.25$

**SUMMARY OF LOW-RECYCLING CASES**  
**allowable wall temperatures in degrees C**

	Li	Filibe	SnLi
Tokamak	380	480	590
Spheromak	410	520	630
FRC	480	620	720

FRC is compact, high density

# Future work on liquid wall spheromak

**1-Liquid wall and liquid divertor analysis resulting in evaporation rates**

**2-Edge plasma analysis resulting in allowed compared to expected evaporation rates**

**3-Gun analysis (helicity injection) resulting in denominator of  $Q=P_{\text{fusion}}/P_{\text{gun}}$**

**4-Write report**

# Jet/droplet divertor---status a year ago--->>

Two effects substantially decrease the surface temperature rise on droplets

$$T_{\text{rise}} = 2 P/A (\alpha\tau/\pi)^{0.5}$$

Manangoni effect convects the hot surface to the cold region and induces internal convection

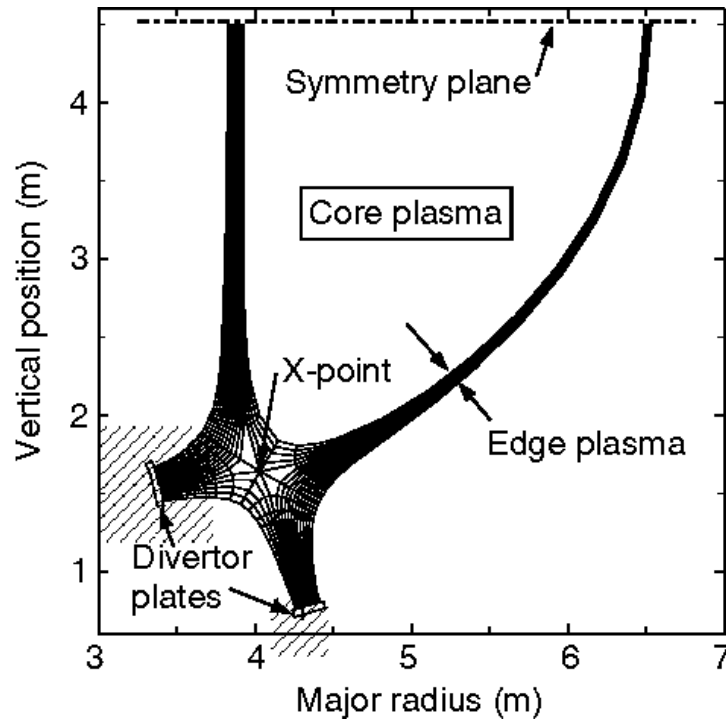

- 1-P/A down factor 4 for area averaging
- 2-Another factor of ??? for convection into the cool interior

**90 MW/m<sup>2</sup> predicted  
Fus. Tech 15 (1989)  
674-679.**

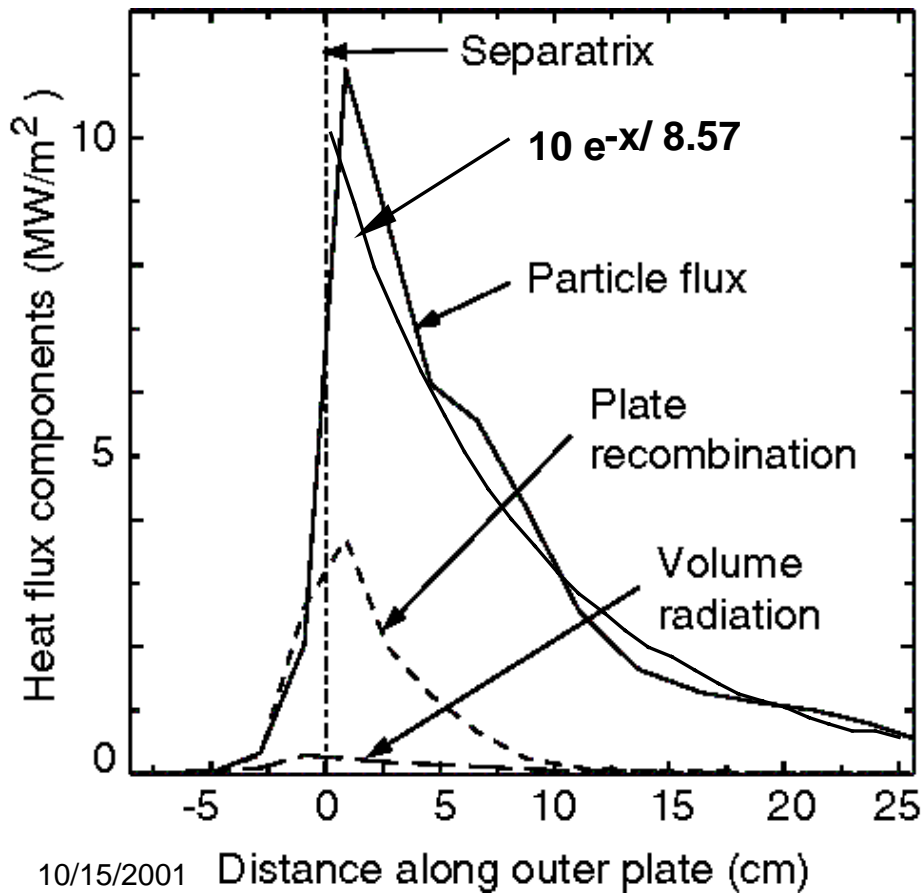

11/10/2000

Evaporation rates will be decreased

# Present liquid divertor work-Tokamak geometry- Substitute liquid jets or droplets for divertor plate

From T. Rognien

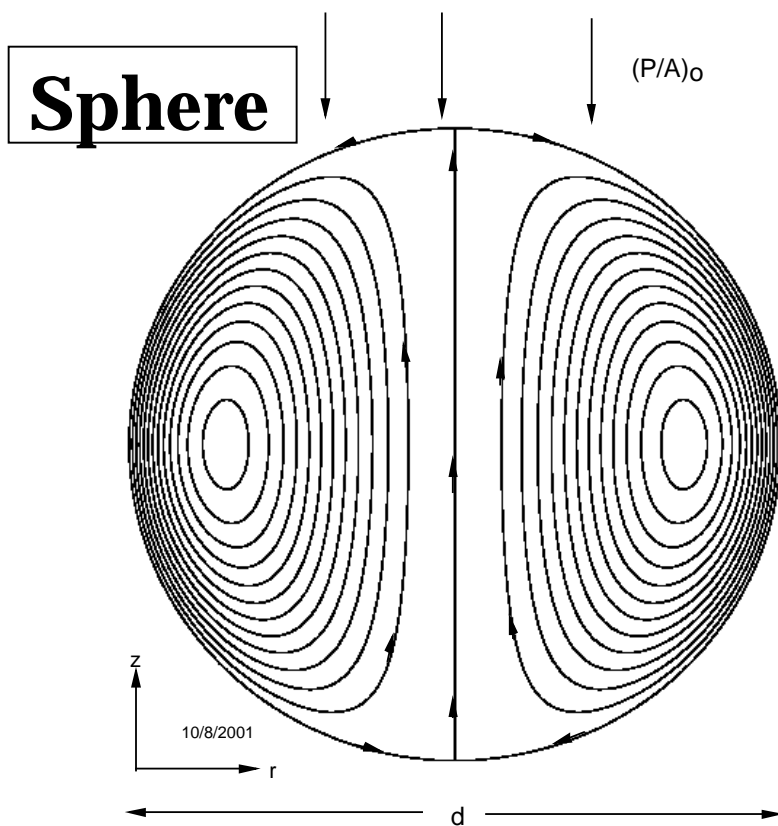

$$(\mathbf{P/A})_{\text{average}} = 3.24 \text{ MW}/\text{m}^2$$

# Geometry and trigonometry are important!

**Droplets (jets) will have internal circulation due to temperature dependent surface tension (Marangoni effect). This presents  $\approx 4.3$  times the frontal area for spheres and 5.14 times for cylindrical jets.**

**The staggering heat load in the divertor is spread out by a**

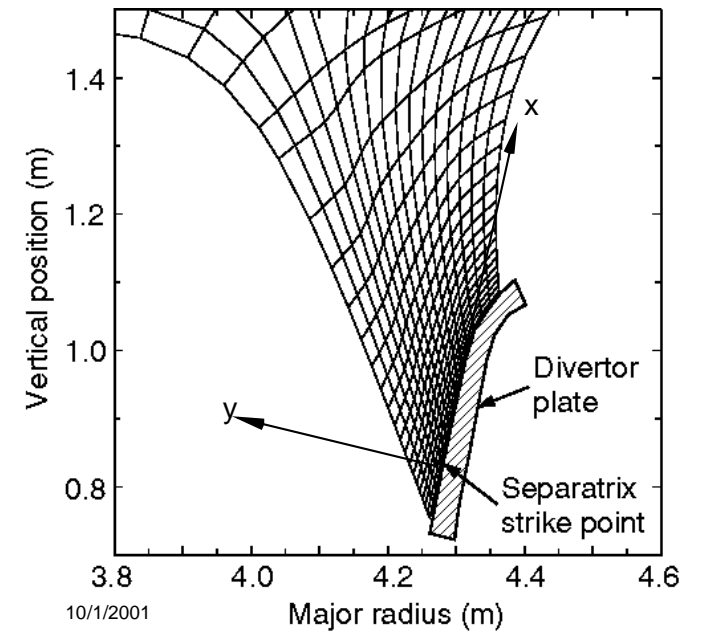

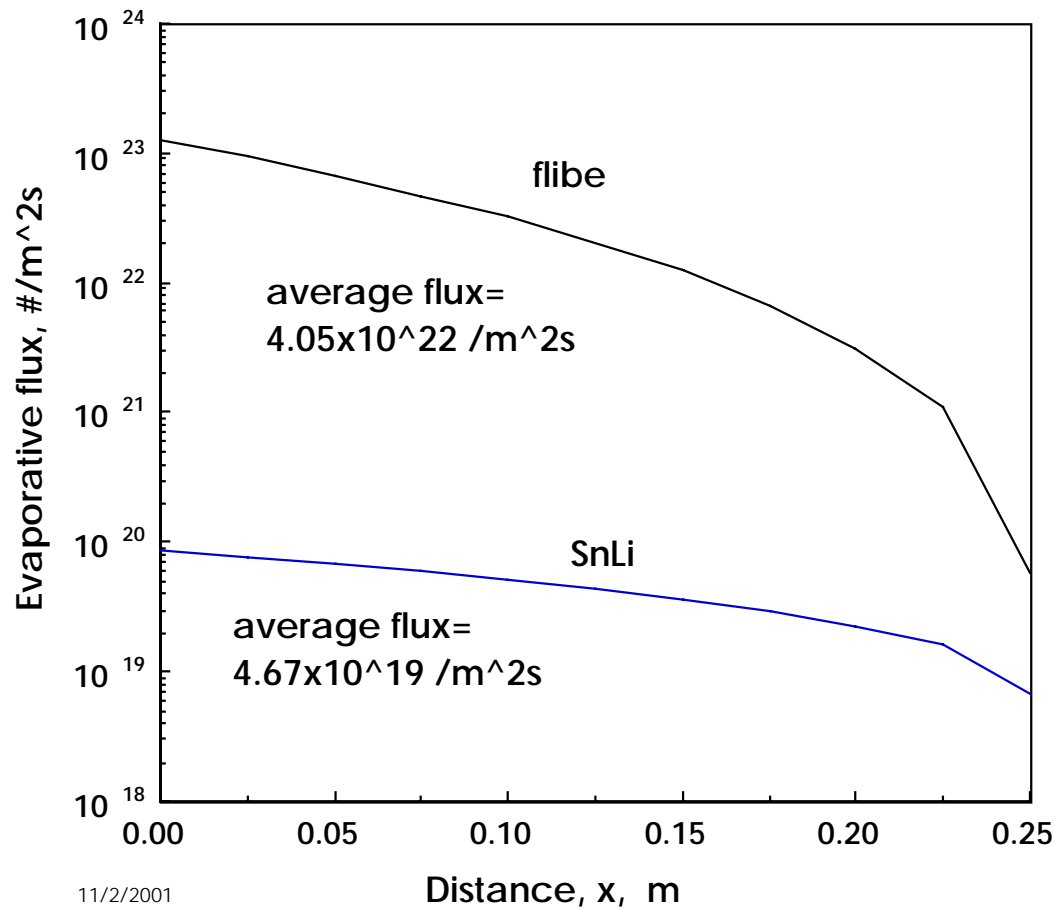

**factor of 4.3 to 5.14!**

# The shallow angle of heat flux results in one jet screening its neighbor.

# Liquid slab reference case, $P/A_{\text{average}} = 3.24 \text{ MW/m}^2$

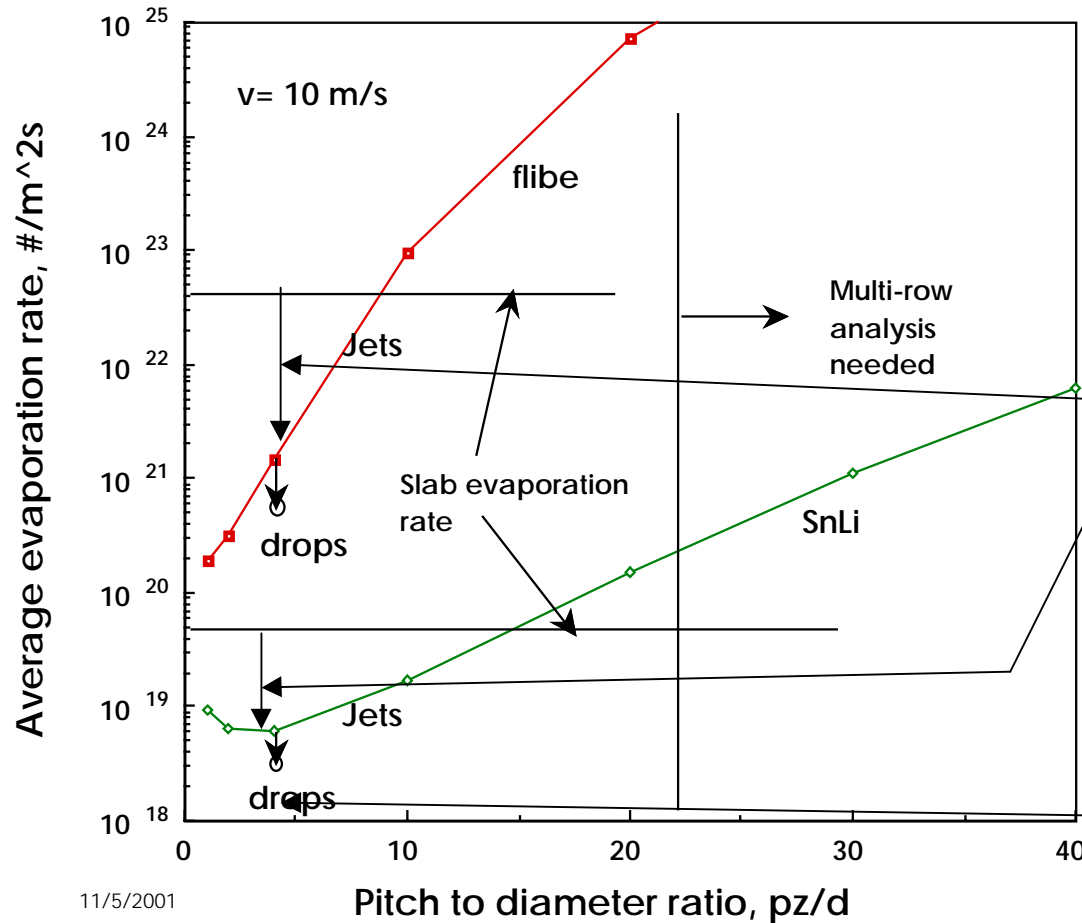

# Simplified model for illustration

## “Square” jets

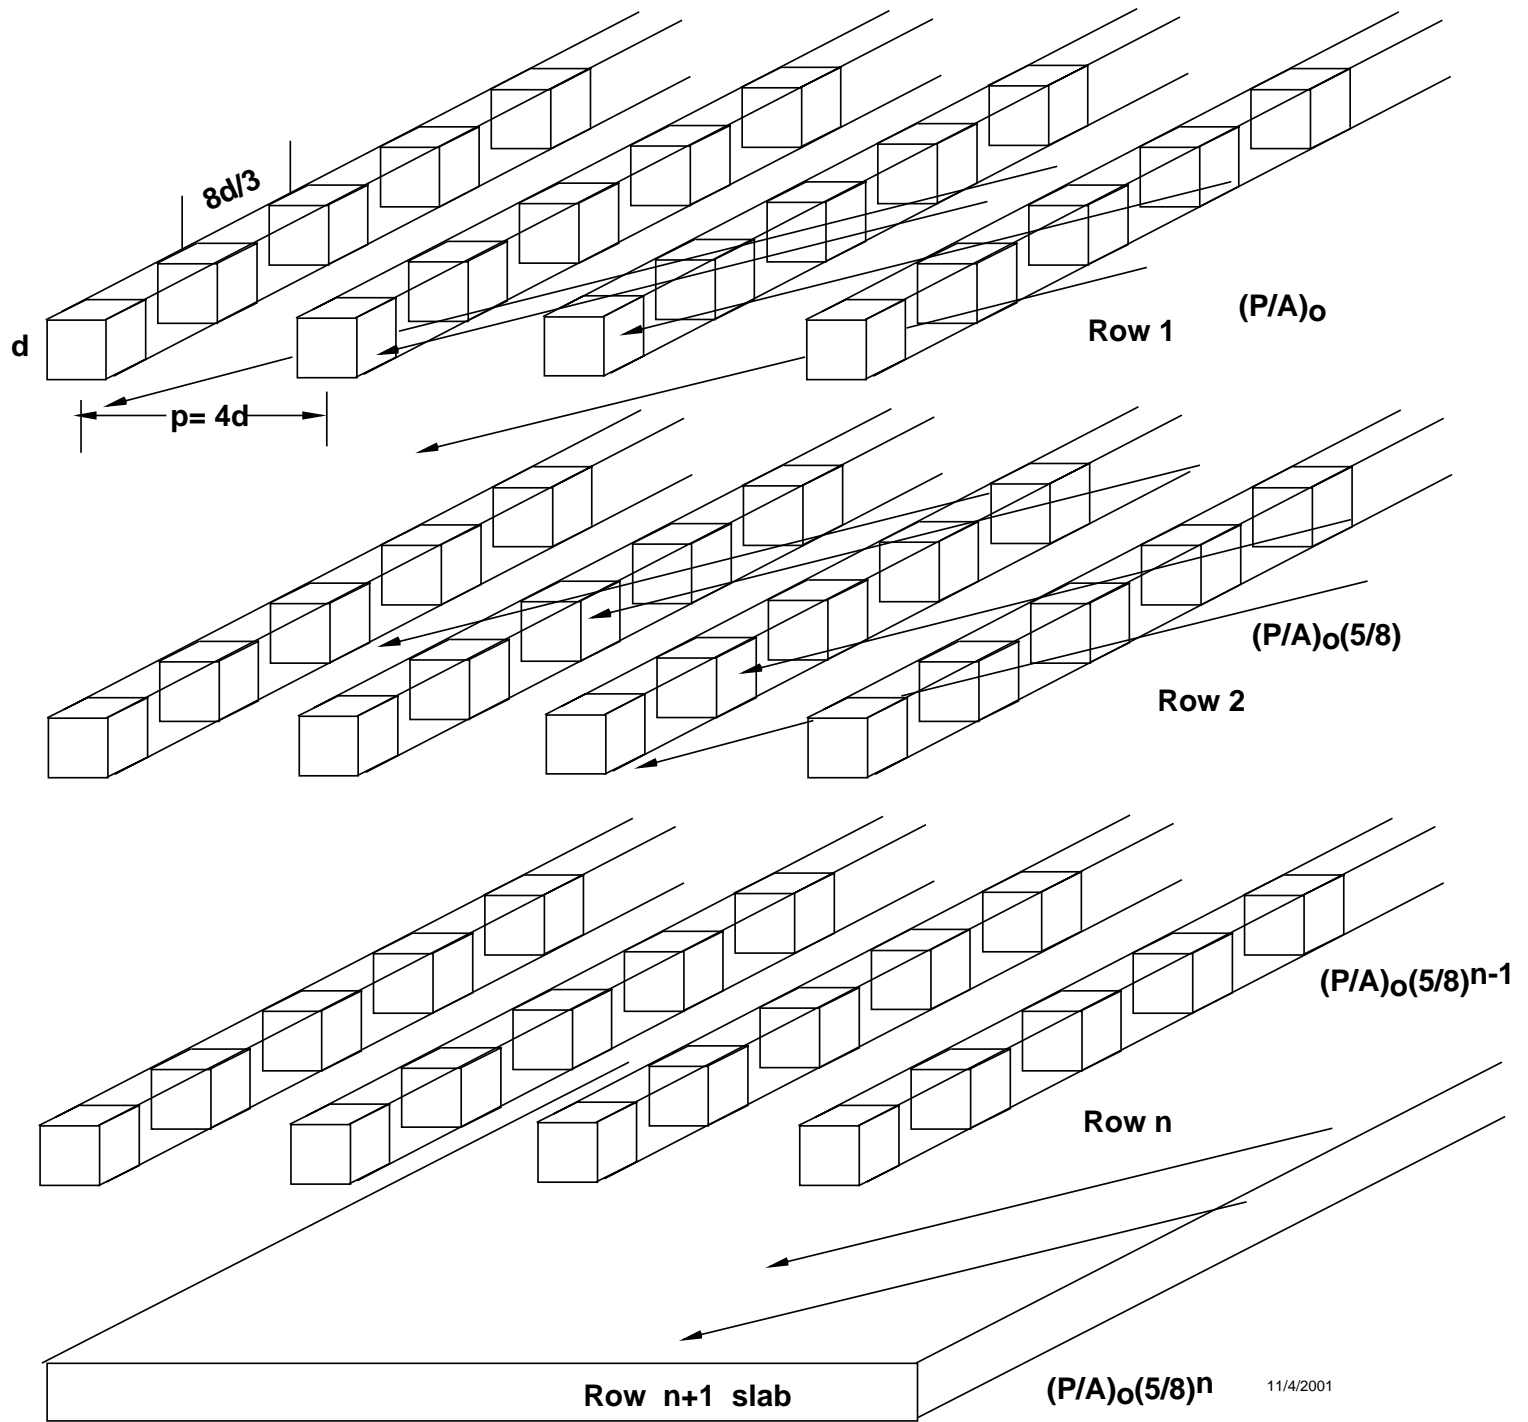

**Model is simplified in many ways**

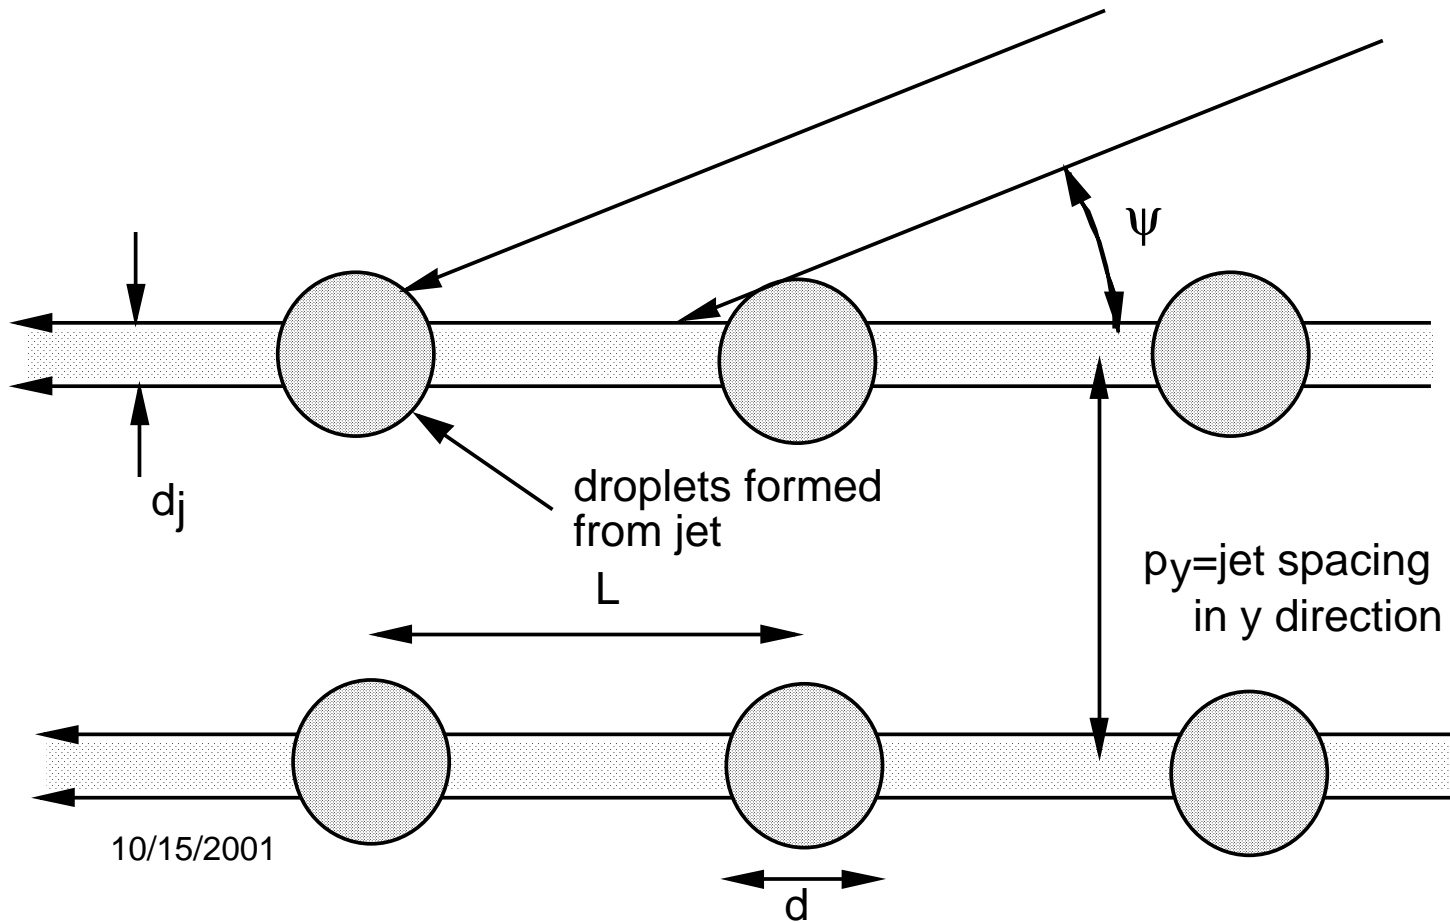

# Evaporation versus pitch between jets

**For  $p/d=4$   
evaporation is  
reduced a factor  
of 28 for flibe and 8  
for SnLi  
compared to a slab.  
Droplets with  
multiple rows**

# Droplet analysis is underway

## Future work

- **Run more geometric variations**
- **Run more liquid cases**
- **Put in time dependent heat flux in calculation**
- **Show jet and droplet dimensions**
- **Put in evaporative cooling correction and others**
- **Work up case of  $\omega = 4.45^\circ$  rather than  $90^\circ$ , that is, jets along field lines**
- **Work up circulation rate due to convection**
- **Include MHD effect in circulation**
- **Put in condensation correction**

# **Conclusions**

---

**Jets and droplets seem to have a big advantage over a liquid slab by spreading the incident power over more area and causing half or more of the evaporation to go away from the plasma.**

**The resulting surface temperature rise is reduced by a factor of several, which reduces evaporation.**
