

ECE7252

Statistical Learning for Signal Processing

Lecture 2: Probability Theory Essentials

Chin-Hui Lee

School of Electrical and Computer Engineering

Georgia Institute of Technology

Atlanta, GA 30332, USA

chl@ece.gatech.edu

Textbook: Contents and Study Subjects

- Overview of Supervised Learning
- Linear Methods for Regression
- Linear Methods for Classification
- Basis Expansion for Regularization
- Kernel Method
- Model Assessment and Selection
- Model Inference and Averaging
- Additive Method, Trees, and Related Methods
- Boosting and additive trees
- Neural Networks
- SVM and Flexible Discriminants
- Prototype Methods and Nearest Neighborhood
- Unsupervised Learning

Probability Tools: An Overview

- Why probabilistic approach?
 - Probabilistic vs. deterministic description of *events*
 - Model-based vs. rule-based *inference* (scores)
 - A natural way to summarize a large collection of data with a small set of parameters (*corpus-based*)
 - Taking advantage of existing theory and methods
 - Moving from subjective to *objective evaluation*
 - Moving from theory to *computation and realization*
- Historic Perspective
 - Speech science vs. statistical approach
 - New trend in computational linguistics and media
 - Combining rules and models: a win-win story

Some Definitions

- Sample Space: Ω
 - collection of all possible observed outcomes
- Sample Event: $A \in \Omega$ including null event ϕ
- σ -field: set of all possible events $A \in F_\Omega$
- Probability Function (Measurable) $P: F_\Omega \rightarrow [0,1]$
- Three Axioms:
 - $P(\phi) = 0$ $P(\Omega) = 1$
 - If $A \subseteq B$ then $P(A) \leq P(B)$
 - If $A \cap B = \phi$ then $P(A \cup B) = P(A) + P(B)$

Some Examples

- Sample Space:
 - $\Omega_c = \{x: x \text{ is the height of a person on earth}\}$
 - $\Omega_d = \{(y, z): y \text{ is the age and } z \text{ is resident city}\}$
- Sample Event:
 - $A = \{x: x > 200\text{cm}\}$
 - $B = \{x: 120\text{cm} < x < 130\text{cm}\}$
 - $C = \{(\text{teens}; \text{Shenzhen or Hong Kong})\}$
 - $D = \{(\text{over } 70; \text{Japan})\}$
- σ -field: set of all possible events F_Ω
- Probability Function (Measurable) $P: F_\Omega \rightarrow [0,1]$
 - measuring A, B, C and D; computing $P(A)$, $P(B)$, $P(C)$ and $P(D)$; inference about A, B, C, and D

Conditional Events

- *Prior Probability*

- Probability of an event before considering any additional knowledge or observing any samples

- *Conditional Probability* $P(A|B) = P(A \cap B) / P(B)$

- updated probability of an event given some knowledge about another event: $P(A|B)$

- *Prove the Addition Rule: $P(A \cup B) = P(A) + P(B) - P(A \cap B)$*

- *From Multiplication Rule, Show Chain Rule:*

$$P(A_1 \cap A_2 \cap \dots \cap A_n) = P(A_1)P(A_2 | A_1) \cdots P(A_n | \bigcap_{i=1}^{n-1} A_i)$$

- *Approximating Language Probabilities:*

$$P(W) = P(w_1)P(w_2 | w_1) \cdots P(w_{|W|} | w_1, \dots, w_{|W|-1})$$

$$\approx P(w_1)P(w_2 | w_1) \prod_{i=3}^{|W|} P(w_i | w_{i-1}, w_{i-2}) \quad n - \text{gram}$$

Bayes' Theorem

- Swapping dependency between events
 - Calculate $P(B|A)$ in terms of $P(A|B)$ that is available and more relevant in some cases
- In many cases, not important to compute $P(A)$

$$P(B|A) = \frac{P(B \cap A)}{P(A)} = \frac{P(A|B)P(B)}{P(A)}$$

$$\arg \max_B \frac{P(A|B)P(B)}{P(A)} = \arg \max_B P(A|B)P(B)$$

- Another Form of Bayes' Theorem (try $n=2$)
 - If a set B partitions A , i.e. $A = \bigcup_{i=1}^n B_i$ $B_i \cap B_k = \phi$

$$P(B_j|A) = \frac{P(A|B_j)P(B_j)}{P(A)} = \frac{P(A|B_j)P(B_j)}{\sum_{i=1}^n P(A|B_i)P(B_i)}$$

Random Variables and Vectors

- A function that maps sample space to a n-dimensional space of real numbers for easy manipulation (sample space can be irregular)
 - linking events to numerical values $X : \Omega \rightarrow \mathfrak{R}^n$

Discrete Random Variables

- Mapping events to a subset of integers, e.g. *Bernoulli trial*: 0 for success and 1 for failure (*binomial* distribution)
- Probability Mass Function (pmf)

$$p(x) = p(X = x) = P(A_x) \quad \text{with} \quad A_x = \{\omega \in \Omega : X(\omega) = x\}$$

$$\sum_i p(x_i) = \sum_i P(A_{x_i}) = P(\Omega) = 1$$

- Exercise: define a random variable as the product of the dots on two dices, derive the outcome space of the r.v. and derive the pmf

Display of Probability Mass Function

- Binomial distribution: $n=3$, $p=0.7$ (success rate)

$$B(r; n, p) = \frac{n!}{r!(n-r)!} p^r (1-p)^{n-r} \quad \text{where } 0 \leq r \leq n$$

Can you plot the pmf for other value pairs of (n, p) ?

Continuous Random Variables

- Mapping events to real numbers
- Probability Density Function (pdf): $f(x)$

$$P(a \leq x \leq b) = \int_a^b f(x)dx \quad P(\Omega) = \int_{-\infty}^{\infty} f(x)dx = 1$$

- Probability Distribution Function

$$F(y) = \int_{-\infty}^y f(x)dx \quad F(-\infty) = 0 \quad F(\infty) = 1$$

Function of Random Variables

- A function of r.v.'s is also a r.v.
 - e.g. $X=U+V+W$, if we know $f(u,v,w)$ how about $f(x)$?
 - e.g. sum of dots on two dices
- Random functions are often useful to describe random events based on r.v.'s
- Problems are easier for known and popular r.v.'s
 - e.g. if U & V are independent Gaussian, so is $X=U+V$
 - e.g. if W & Z are independent uniform, is $Y=W+Z$?

Joint and Conditional Distribution

- Joint Event and Product Space $\Omega_c \times \Omega_d$
 - e.g. $E=(A,B)=(200\text{cm}<\text{height, live in Pakistan})$
- Joint pmf and pdf of two random variables
$$p(x, y) = P(X = x, Y = y) \quad P(a \leq x \leq b, c \leq y \leq d) = \int_a^b \int_c^d f(x, y) dy dx$$
- Marginal pmf and pdf $p(x) = \sum_y p(x, y) \quad f(x) = \int f(x, y) dy$
- Conditional pmf and pdf
$$p(x|y) = p(x, y) / p(y) \quad f(x|y) = f(x, y) / f(y)$$
- Conditional Mean: $\text{Mean}(X | Y = y) = \int xf(x|y) dx$
- Independence: $f(x, y) = f(x)f(y) \quad f(x|y) = f(x)$

Mathematical Expectation

- Expectation of Random Functions

$$E(q(X)) = \int_{-\infty}^{\infty} q(x) f(x) dx \quad \text{or} \quad \sum_i q(x_i) p(x_i)$$

- Mean and Variance

$$E(\bar{X}) = \mu \quad \text{Var}(\bar{X}) = \sigma^2 / n$$

$$\text{Mean}(X) = E(X) \quad \text{Var}(X) = E([X - E(X)]^2)$$

- Covariance between two r.v.'s

$$\text{Cov}(X, Y) = E([X - E(X)][Y - E(Y)])$$

- Conditional Expectation

$$E(q(X) | Y = y) = \int_{-\infty}^{\infty} q(x) f(x | y) dx \quad \text{or} \quad \sum_i q(x_i) p(x_i | y)$$

- Show the sample mean of n independent samples of Gaussian r.v.'s is also Gaussian:

Bayes' Theorem

- Swapping dependency between events
 - calculate $P(B|A)$ in terms of $P(A|B)$ that is available and more relevant in some cases
- In many cases, it is not important to compute $P(A)$

$$P(B|A) = \frac{P(B \cap A)}{P(A)} = \frac{P(A|B)P(B)}{P(A)}$$

$$\arg \max_B \frac{P(A|B)P(B)}{P(A)} = \arg \max_B P(A|B)P(B)$$

- Another Form of Bayes' Theorem (try $n=2$)
 - If a set B partitions A , i.e. $A = \bigcup_{i=1}^n B_i$ $B_i \cap B_k = \phi$

$$P(B_j|A) = \frac{P(A|B_j)P(B_j)}{P(A)} = \frac{P(A|B_j)P(B_j)}{\sum_{i=1}^n P(A|B_i)P(B_i)}$$

Some Useful Distributions (I)

- *Binomial* Distribution: $B(R=r; n, p)$
 - Probability of r successes in n trials with a success rate p

$$B(r; n, p) = \frac{n!}{r!(n-r)!} p^r (1-p)^{n-r} \quad \text{where } 0 \leq r \leq n$$

- *Multinomial* Distribution

$$M(r_1, \dots, r_m; n, p_1, \dots, p_m) = \frac{n!}{r_1! \cdots r_m!} \prod_{i=1}^m p_i^{r_i} \quad 0 \leq r_i \quad \sum_{i=1}^m r_i = n$$

- Show:

$$\sum_{r=0}^n B(r; n, p) = 1 \quad \text{and} \quad E_B(R) = \sum_{r=0}^n r B(r; n, p) = np$$

- Can you compute $\text{Var}(R)$? Any explanation?

Some Useful Distributions (II)

- *Uniform Distribution: $U(X=x; a, b)$*

$$U(x; a, b) = \begin{cases} 1/(b-a) & a \leq x \leq b \\ 0 & \text{otherwise} \end{cases} \quad \text{with } a < b$$

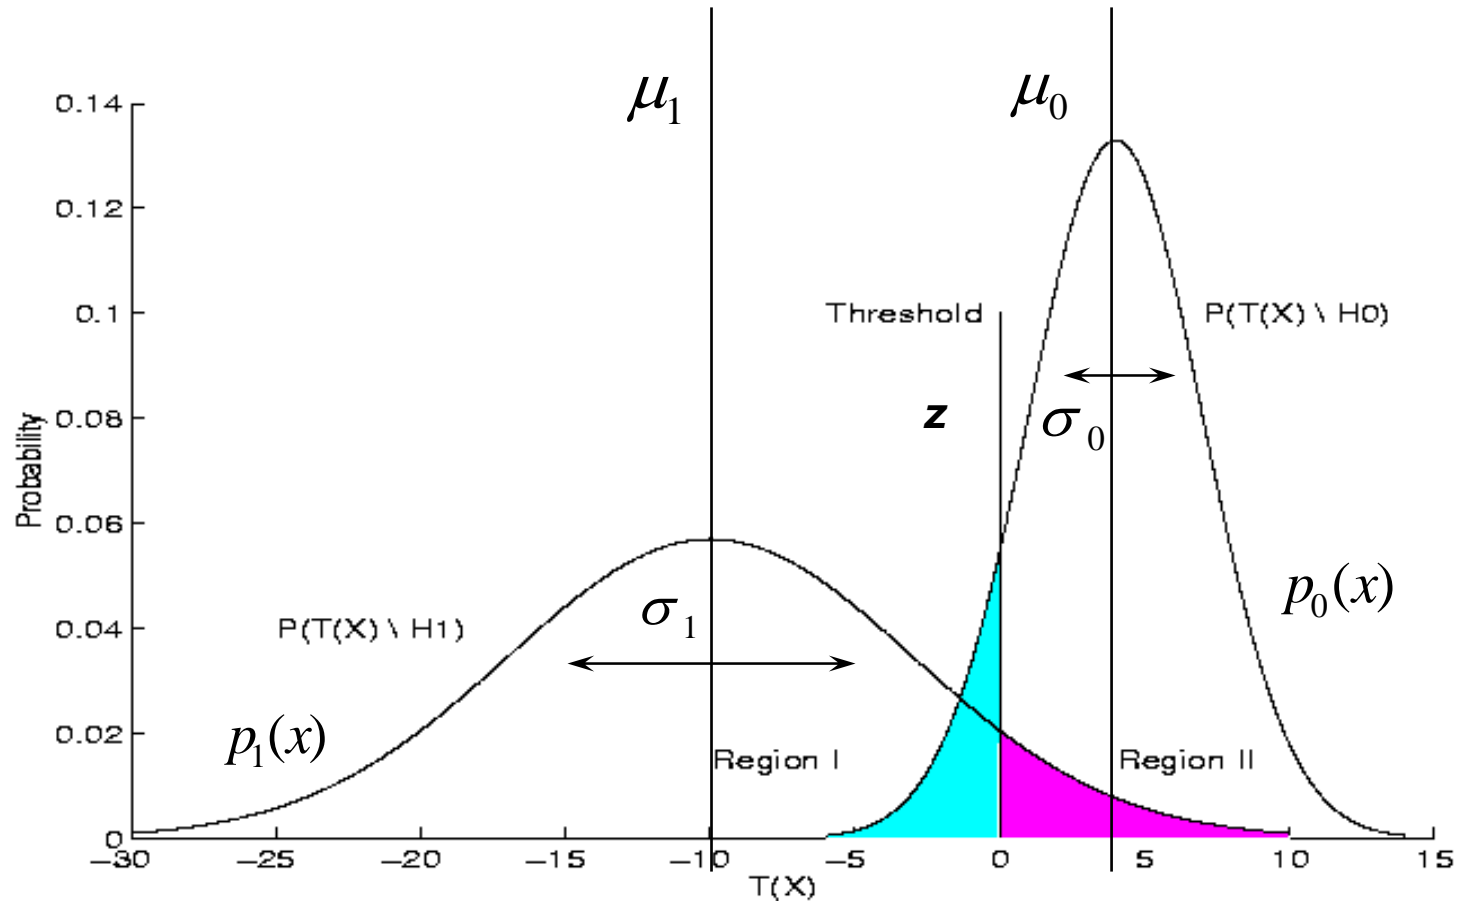

- *Normal (or Gaussian) Distribution: Bell Curve*

$$N(x; \mu, \sigma^2) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-(x-\mu)^2/2\sigma^2} \quad -\infty < x < \infty \quad \sigma > 0$$

- Show $E_U(X) = \frac{(b+a)}{2}$ and $E_N(X) = \mu$

- Can you compute their variances? $\text{VAR}_U(X)$ and $\text{VAR}_N(X)$

Typical Normal Distributions

Standard deviation (s.d. or spread): $\sigma_0 < \sigma_1$

Some Useful Distributions (III)

- *Multivariate Normal Distribution:*

$$N(\mathbf{x}; \boldsymbol{\mu}, \mathbf{C}) = \frac{1}{\sqrt{(2\pi)^n |\mathbf{C}|}} e^{-\frac{1}{2}(\mathbf{x}-\boldsymbol{\mu})^t \mathbf{C}^{-1}(\mathbf{x}-\boldsymbol{\mu})} \quad -\infty < \mathbf{x} < \infty$$

- Show: $E_N(\mathbf{X}) = \boldsymbol{\mu}$ and $\text{VAR}_N(\mathbf{X}) = \mathbf{C}$
- Can you write down the bivariate normal distribution form, compute $\text{Cov}(X, Y)$, and derive the marginal and conditional densities, $f(y)$ and $f(x|y)$?

$$\mathbf{x} = \begin{bmatrix} x \\ y \end{bmatrix} \quad \boldsymbol{\mu} = \begin{bmatrix} \mu_x \\ \mu_y \end{bmatrix} \quad \mathbf{C} = \begin{bmatrix} \sigma_x^2 & r\sigma_x\sigma_y \\ r\sigma_x\sigma_y & \sigma_y^2 \end{bmatrix}$$

Some Useful Distribution (IV)

- Uniform distribution over all directions

$$U(\theta; -\pi, \pi) = \begin{cases} 1/2\pi & -\pi \leq \theta \leq \pi \\ 0 & \text{otherwise} \end{cases}$$

- Uniform distribution on a circle

$$U(r, \theta; 0, R, -\pi, \pi) = \begin{cases} 1/\pi R^2 & -\pi \leq \theta \leq \pi, 0 \leq r \leq R \\ 0 & \text{otherwise} \end{cases}$$

- *2-D Uniform Distribution*

$$U(x, y, a, b, c, d) = \begin{cases} 1/(b-a)(d-c) & a \leq x \leq b, c \leq y \leq d \\ 0 & \text{otherwise} \end{cases} \quad \text{with } a < b, c < d$$

Sum of Many Random Variables

- Show average of two independent samples of uniform r.v.'s form a triangular shape pdf. How about sample mean of n samples? Can you imagine what it will be like for very large n ?

- *Law of large numbers* – Asymptotic Normal pdf !!

Distributions of Random Variables

- Parametric distributions
 - r.v. described by a small number of parameters in pdf/pmf
 - e.g. Gaussian (2), Binomial (3), 2-d uniform (3 or 4)
 - many useful and known parametric distributions
 - distributions of independently and identically distributed (i.i.d.) samples from such distributions are easier to derive
- Non-Parametric distributions
 - usually described by the data samples themselves
- Sample distribution & histogram (pmf / bar chart)
 - counting samples in equally-sized bins and plot them

Gaussian Mixture Model (GMM)

$$MG(x) = \sum_{m=1}^M \omega_m N(x; \mu_m, \sigma_m^2) \quad \sum_{m=1}^M \omega_m = 1 \quad 0 < \omega_m < 1 \quad \sigma_i > 0$$

- In theory, $MG(x)$ can be used to approximate any density up to second order statistics (mean and variance)
- Multi-mode densities are more likely to describe real-world data better than single-mode densities
- Compute:
 $E_{MG}(X)$ and $VAR_{MG}(X)$

Statistics and Probability

- *Statistic*: a function of random samples
 - E.g. sample mean and variance
- *Sufficient Statistics*
 - A minimum set of summary statistics to describe the samples without losing any information, e.g. sample mean, variance, and size for Gaussian samples
 - For some r.v.'s, the sufficient statistics can only be described by the entire set of data samples
 - Distributions of sufficient statistics are often reproducible which are keys to Bayesian estimation with conjugate prior and posterior pairs

Some Useful Descriptive Statistics

- Sampling theory and descriptive statistics
 - From partial observations to overall assessment
- Sample size, mean, variance (margin of error)
- Range, maximum, minimum
- Median, percentile, upper and lower quartiles
- Descriptive statistics are often seen in many articles and reports in our daily lives. Do you know how to evaluate them and judge their validity when certain conclusions are drawn?

The Art and Science of Sampling

- A few examples
 1. Randomly selecting n out of M vendors in Atlanta for evaluation to award a construction job
 2. Randomly polling Q households for TV rating
 3. Randomly selecting parts for error measurement
 4. Opinion polls: done a lot in election seasons
 5. Sending pilot signals to probe a wireless connection
- Questions
 - How many to sample? What's the population like?
 - What can be said about the sampling results?
 - How to use probability theory to help?
 - How to use computer simulation in sampling?

(Empirical) Sample Mean & Variance

- Population: collection of data being studied
 - N : Size of the population (typically a large size)
 - (Random) Sample: n is the size of the sample set: $\{x_1, x_2, \dots, x_n\}$ with x_i 's independent samples from the set
- Statistic: function of samples (statistical inference)
 1. Sample Mean (not the mean parameter):
$$\bar{x} = \frac{1}{n} \sum_{i=1}^n x_i \quad \text{or} \quad \hat{X} = \frac{1}{n} \sum_{i=1}^n X_i \quad (X_i \text{ is any r. v. with a pdf } f(x))$$
 2. Sample Variance (r. v., not the variance parameter):

$$S_1^2 = \frac{1}{n} \sum_{i=1}^n (X_i - \bar{X})^2, \quad S_2^2 = \frac{1}{n} \sum_{i=1}^n (X_i - \hat{X})^2, \quad \text{or} \quad \tilde{S}_2^2 = \frac{1}{n-1} \sum_{i=1}^n (X_i - \hat{X})^2$$

Important Statistics & Expectations (I)

1. Expectation of sample mean:

$$E[\hat{X}] = \frac{1}{n} \sum_{i=1}^n E[X_i] = \frac{1}{n} \sum_{i=1}^n \bar{X} = \bar{X} \text{ (unbiased statistic of } \bar{X}\text{)}$$

2. Expectation of sample variance (known mean/variance):

$$\begin{aligned} E\{S_1^2\} &= E\left[\frac{1}{n} \sum_{i=1}^n (X_i - \bar{X})^2\right] = \frac{1}{n} \left\{ \sum_{i=1}^n E(X_i)^2 - 2 \sum_{i=1}^n E(X_i * \bar{X}) + n\bar{X}^2 \right\} \\ &= \frac{1}{n} \{nE(\bar{X}^2) - n\bar{X}^2\} = \frac{n}{n} [\bar{X}^2 - (\bar{X})^2] = \sigma^2 \end{aligned}$$

Note: $E[X_i X_j] = E[X^2]$ ($i = j$), and $E[X_i X_j] = (E[X])^2 = \bar{X}^2$ ($i \neq j$)

Important Statistics & Expectations (II)

3. Expectation of sample variance (unknown parameters):

$$\begin{aligned} \text{Biased statistic: } E\{S_2^2\} &= E\left[\frac{1}{n} \sum_{i=1}^n (X_i - \hat{X})^2\right] = E\left\{\frac{1}{n} \sum_{i=1}^n \left[X_i - \frac{1}{n} \sum_{j=1}^n X_j\right]^2\right\} \\ &= \frac{1}{n} \left\{ \sum_{i=1}^n E[(X_i)^2] - 2 \sum_{i=1}^n E\left(X_i * \frac{1}{n} \sum_{j=1}^n X_j\right) + \frac{1}{n^2} \sum_{i=1}^n E\left[\left(\sum_{j=1}^n X_j\right)\left(\sum_{k=1}^n X_k\right)\right] \right\} \\ &= \frac{1}{n} \left\{ \sum_{i=1}^n E[(X_i)^2] - 2 \frac{1}{n} \sum_{i=1}^n E[(X_i)^2] - \frac{2}{n} E\left[\sum_{i \neq j} \sum_{j=1}^n X_i X_j\right] + \frac{1}{n} E\left[\left(\sum_{i=1}^n X_i\right)\left(\sum_{j=1}^n X_j\right)\right] \right\} \\ &= \frac{1}{n} \left\{ nE(X^2) - E(X^2) - (n-1)[E(X)]^2 \right\} = \frac{n-1}{n} \left\{ E[(X - \bar{X})^2] \right\} = \frac{n-1}{n} \sigma^2 \end{aligned}$$

4. Unbiased sample variance:

$$E(\tilde{S}_2^2) = \frac{n}{n-1} E(S_2^2) = \sigma^2$$

Other Properties on Statistics

5. Variance of sample variance (unknown parameters):

$$\text{Var}[S_2^2] = E\{[S_2^2 - E(S_2^2)]^2\} = \frac{E[(X - \bar{X})^4] - \sigma^4}{n} = \frac{\mu_4 - \sigma^4}{n} \quad (\text{your exercise})$$

- Sample mean and sample variance are correlated random variables useful for statistical inference
 - their joint density can be established (not in ECE3075)
- The same discussion can be extended to multivariate cases (studies have been completed for Gaussian cases)
- Discussion on population size N (for your reading)
 - Sampling with or without replacement
- Large sample theory ($n > 30$, depending on individual cases)

Sampling Distributions (I)

- For many applications, it is important to obtain the distribution of a sample statistic. We need to watch for assumptions about the random samples before we work out sample distributions.
 - realize what's known and unknown
- Example 1: Normalized Sample Mean
 - independent Gaussian samples with known variance

$$\hat{\bar{X}} = \frac{1}{n} \sum_{i=1}^n X_i \text{ is Gaussian with mean } \bar{X} \text{ and variance } \frac{\sigma^2}{n}$$

$$Z = \frac{\hat{\bar{X}} - \bar{X}}{\sigma/\sqrt{n}} \text{ is Gaussian with mean 0 and variance 1 (standardized r. v.)}$$

- note: Z can not be defined if we don't know the parameters

Sampling Distributions (II)

- Example 2: Normalized Sample Mean
 - independent Gaussian samples with unknown variance

$$T = \frac{\hat{X} - \bar{X}}{\tilde{S}_2 / \sqrt{n}} = \frac{\hat{X} - \bar{X}}{S_2 / \sqrt{n-1}} \text{ has a } \textit{Student's t-distribution} \text{ with } n-1 \text{ degrees of freedom}$$

- The pdf of T (assuming $v=n-1$) is of the form

$$f_T(t) = \frac{\Gamma(\frac{v+1}{2})}{\sqrt{v\pi}\Gamma(\frac{v}{2})} \left(1 + \frac{t^2}{v}\right)^{-\frac{v+1}{2}} \text{ (Figure 4-2, } v=1, \Gamma(v) \text{ is the Gamma function)}$$

- for large value of v , we have an approximate Gaussian

$$\Gamma(v+1) = v\Gamma(v), \Gamma(k+1) = k! \text{ (integer } k), \Gamma(2) = \Gamma(1) = 1, \Gamma(1/2) = \sqrt{\pi}$$

Correlation between Two Sets of Data

- Linear correlation coefficient (Pearson's r)

$$r = \frac{\sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^n (x_i - \bar{x})^2} * \sqrt{\sum_{i=1}^n (y_i - \bar{y})^2}} \quad \text{with } \bar{x} = \frac{1}{n} \sum_{i=1}^n x_i, \bar{y} = \frac{1}{n} \sum_{i=1}^n y_i$$

- Pearson's r approaches Gaussian for large n
 - significance of the value of r : small r is often meaningless unless the sample size n is large, and $f(x, y)$ is known
 - large r implies a tighter coupling between X and Y

Statistical Inference

- Probability Theory Tools
 - Fuzzy description of phenomena
 - Statistical modeling of data for inference
- Statistical Inference Problems
 - *Classification*: choose one of the stochastic sources
 - *Decision* and *Hypothesis Testing*: comparing two stochastic assumptions and decide on how to accept one of them
 - *Estimation*: given random samples from an assumed distribution, find “good” guess for the parameters
 - *Prediction*: from past samples, predict next set of samples
 - *Regression (Modeling)*: fit a model to a given set of samples
- From theory to many real-world applications

Maximum Likelihood Estimation for Gaussians

- Given iid samples from a normal distribution, what's their joint density (likelihood)?

$$f(x_1, \dots, x_n) = \prod_{i=1}^n f(x_i) = \frac{1}{(\sqrt{2\pi\sigma^2})^n} \exp\left[-\frac{1}{2\sigma^2} \sum_{i=1}^n (x_i - \mu)^2\right]$$

- It can be shown that the sample mean has also a normal distribution, can you derive the density?

$$f\left(\sum_{i=1}^n x_i / n\right) = f(y) = \frac{1}{\sqrt{2\pi\sigma^2 / n}} \exp\left[-\frac{n}{2\sigma^2} (y - \mu)^2\right]$$

- Suppose the mean needs to be estimated from the iid samples, show the sample mean is the *maximum likelihood* (“best”) estimate of μ ?
- ML is the most frequently used estimation method

$$\operatorname{argmax}_{\mu} f(x_1, \dots, x_n | \mu) = \operatorname{argmax}_{\mu} \log[f(x_1, \dots, x_n | \mu)]$$

Maximum Likelihood Estimation of N -grams

- Properties of n -grams

$$P(w_n | w_1, \dots, w_{n-1}) = \frac{P(w_1, \dots, w_{n-1}, w_n)}{P(w_1, \dots, w_{n-1})},$$

$$\sum_{w_n \in V} P(w_n | w_1, \dots, w_{n-1}) = 1,$$

$$\sum_i C(e_i) = N_n \quad e_i : i\text{-th event}$$

- *MLE of Multinomial Distribution Parameters*

$$P_{MLE}(w_1, \dots, w_{n-1}, w_n) = \frac{C(w_1, \dots, w_{n-1}, w_n)}{N_n},$$

$$P_{MLE}(w_n | w_1, \dots, w_{n-1}) = \frac{C(w_1, \dots, w_{n-1}, w_n)}{C(w_1, \dots, w_{n-1})},$$

$$\sum_{W \in V} C(w_1, \dots, w_{n-1}, W) = C(w_1, \dots, w_{n-1})$$

Hypothesis Testing

- Testing statistical hypotheses
 - Decisions in accepting an assumed distribution from test data
 - What is the level of confidence in accepting right decisions?
 - What is the penalty, if any, for making wrong decisions?
- Formulating **statistical tests**
 - one-sided test: mean = 1000 vs. mean > 1000
 - two-sided test: mean = 1000 vs. mean > 1000 or <1000
 - Many others (textbooks and handbooks)
- Confidence interval and confidence level in testing
 - Larger level of significance corresponds to a more stringent test
- **Confidence measures** for assumed theories

Statistical Hypothesis Testing (I)

- In decision, we usually need to test a hypothesis based on some observation data. The problem is formulated as a test between two complementary hypotheses:
 - H_0 : *null hypothesis*
 - H_1 : *alternative hypothesis*
- Example: Given X_1, X_2, \dots, X_n as a random sample from a Gaussian distribution $N(\mu, \sigma^2)$, where variance σ^2 is known. We need to verify whether its mean is a given value. Thus we do hypothesis testing:
 - $H_0 : \mu = \mu_0$ against $H_1 : \mu \neq \mu_0$

Statistical Hypothesis Testing (II)

- In essence, a hypothesis test will partition the entire observation space into two disjointed parts, C and D
- If an observation X lies in the region C , we reject H_0 ; if X is in D , we accept H_0 . C is called the *critical region*

- *Type I error* (also called *false rejection*) of a test:

$$\alpha = \Pr(E_1) = \Pr(X \in C | H_0)$$

- *Type II error* (also called *false alarm*) of a test:

$$\beta = \Pr(E_2) = \Pr(X \in D | H_1) = 1 - \Pr(X \in C | H_1) = 1 - \gamma$$

Statistical Hypothesis Testing (III)

Neyman Pearson Lemma:

For a simple H_0 and simple H_1 , if the distributions under both H_0 and H_1 are known, i.e., $f_0(X|\theta_0)$ and $f_1(X|\theta_1)$. Given any iid observation data $X=\{X_1, \dots, X_T\}$, at any significance level α , the most powerful test is formulated as:

$$\text{If } LR(X_1^T) = \frac{\prod_{t=1}^T f_0(X_t | \theta_0)}{\prod_{t=1}^T f_1(X_t | \theta_1)} > \tau, \text{ accept } H_0; \text{ otherwise reject } H_0.$$

The threshold τ is adjusted to make the **significance of the test** to be α . If the both pdf's have the same form, the only difference is parameters, The ratio is also called likelihood ratio (LR).

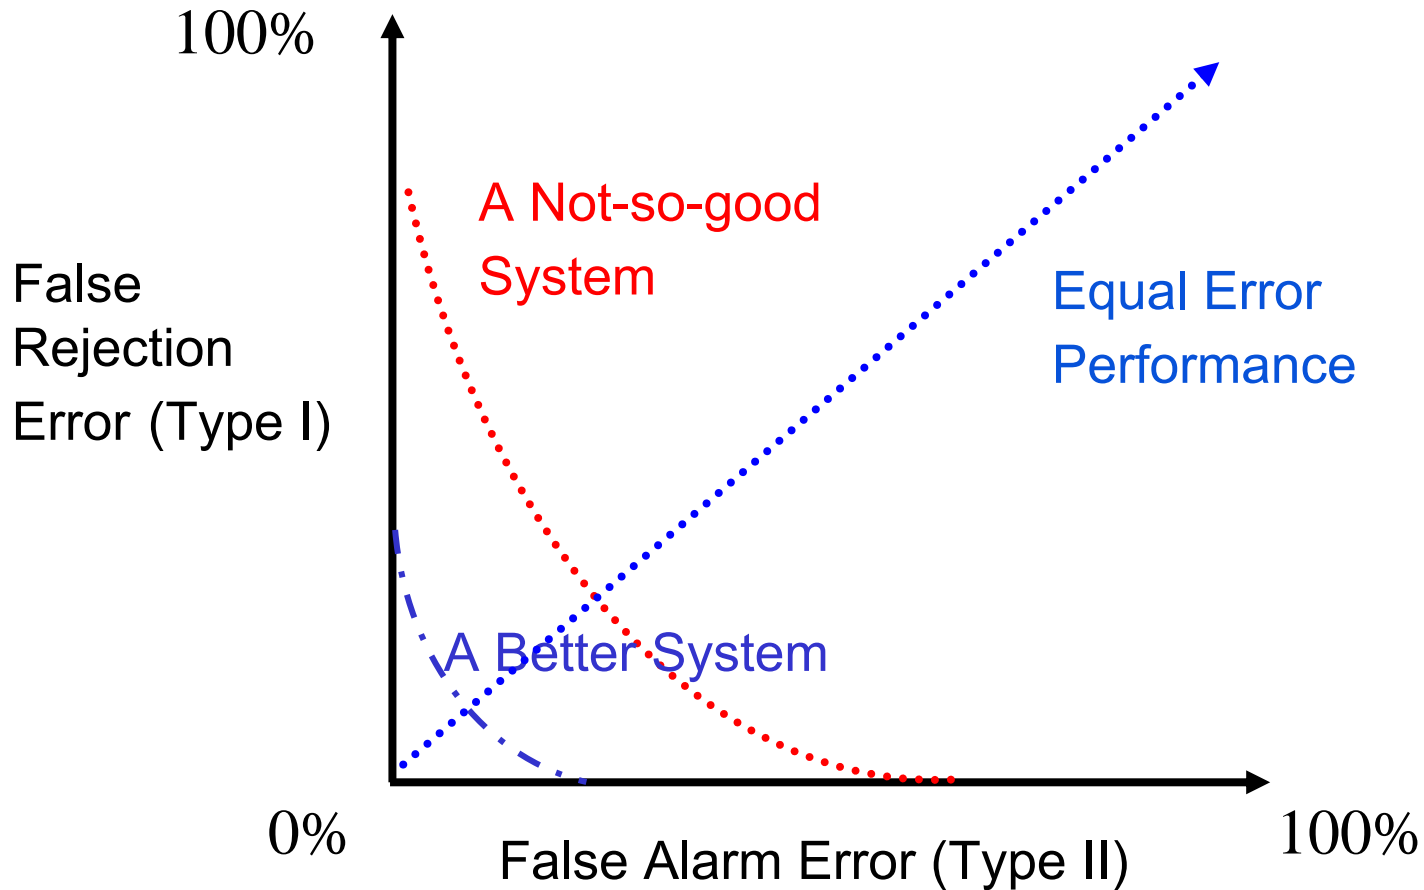

Distributions of Test Statistic T

Evaluating Verification (I)

Evaluating Verification (II): ROC (Receiver Operating characteristic) Curve

Probability Theory Recap

- Parametric vs. non-parametric distributions
 - Parsimonious or extensive description of observed events (model vs. data)
 - Sampling, data storage and sufficient statistics
- Statistical Inference: make sense of data
- Real-world data vs. ideal distributions
 - “There is no perfect goodness-of-fit”
 - Ideal distributions are used for approximation
 - Law of Large Numbers

Summary

- Today's Class
 - Probability and Statistics
 - Web: <http://www.ece.gatech.edu/~chl/ECE7252.sp08>
