

# MACROECONOMICS OF FINANCIAL MARKETS

ECON 712, Fall 2018

Financial Markets and Business Cycles

Guillermo Ordoñez

University of Pennsylvania and NBER

October 15, 2018

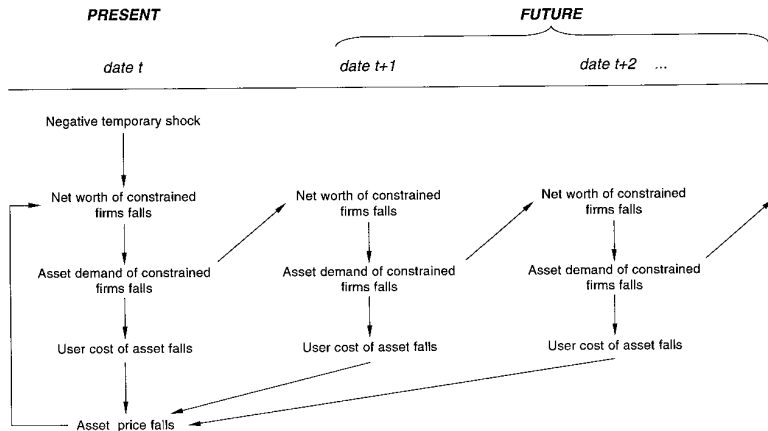

# FINANCIAL FRICTIONS IN MACRO

- Financial markets have the potential to magnify and generate fluctuations.
- Magnification of productivity shocks
  - Collateral constraints  
Kiyotaki and Moore (JPE 97).
  - Costly state verification  
Bernanke and Gertler (AER 89)  
Carlstrom and Fuerst (AER, 97).
- Generation of cycles.
  - Collateral Crises.  
Gorton and Ordonez (AER, 14)

# THE ROLE OF COLLATERAL CONSTRAINTS

- **Main Paper: Kiyotaki and Moore (JPE, 1997)**
- Credit frictions → amplification & persistence of shocks
- Two roles for capital
  - Factor of production
  - Collateral for loans
- Negative productivity shock
  - Reduces output; reduces value of collateral
  - Reduces borrowing, which reduces output further
  - “Multiplier” effects amplifies losses

# MECHANISM SUMMARY

# AGENTS

- Farmers. measure 1

$$E_t \sum_{s=0}^{\infty} \beta^s x_{t+s}$$

- Gatherers, measure  $m$

$$E_t \sum_{s=0}^{\infty} \beta'^s x'_{t+s}$$

- Farmers *more* impatient ( $\beta < \beta'$ )  
(will imply that Farmers are the borrowers in equilibrium)
- Both use land  $k_t$  to produce fruit
- Value of land  $k_t q_t$  used as collateral

# FARMERS

- Farmers' production function for fruit

$$y_{t+1} = (a + c)k_t$$

$ak_t$  = sellable fruit

$ck_t$  = "bruised fruit" which must be consumed

- Investment happens at a rate  $R = \frac{1}{\beta'}$ , then

$$a + c = x + \frac{a - x}{\beta}$$

- Assumption  $a + c > \frac{a}{\beta}$

(farmers do not want to consume more than  $ck_t$ , then sell  $ak_t$ )

## FARMERS (CONSTRAINED)

- Can borrow  $b_t$  at rate  $R$
- Borrowing Constraint (inalienability of farmers' human capital)

$$Rb_t \leq q_{t+1}k_t$$

- Farmers' "flow of funds" constraint

$$(a + c)k_{t-1} + b_t + q_t k_{t-1} = x_t + Rb_{t-1} + q_t k_t$$

$x_t$  is consumption of fruit

## GATHERERS (UNCONSTRAINED)

- They do not have specific skills to threat not paying.
- Gatherers' production function for fruit

$$y'_{t+1} = G(k'_t)$$

$G(\cdot)$  has decreasing returns to scale

- Gatherers' budget constraint

$$G(k'_{t-1}) + b'_t + q_t k'_{t-1} = x'_t + Rb'_{t-1} + q_t k'_t$$

$x'_t$  is consumption of fruit

# EQUILIBRIUM

- Sequences of land prices, allocations of land, debt, consumption for farmers and gatherers

$$\{q_t, k_t, k'_t, b_t, b'_t, x_t, x'_t\}$$

such that everyone's optimizing and markets clearing.

- No uncertainty: perfect foresight

## EQUILIBRIUM RESULTS: FARMERS

- Farmers always borrow the maximum and invest in land

$$b_t = q_{t+1}k_t/R \quad \text{and} \quad x_t = ck_{t-1}$$

- From the budget constraint, farmers' land holdings are

$$k_t = \frac{1}{q_t - q_{t+1}/R} \underbrace{[(a + q_t)k_{t-1} - Rb_{t-1}]}_{\text{net worth}}$$

$$u_t \equiv q_t - q_{t+1}/R = \text{"down payment"}$$

- Farmers spend entire net worth on difference between price of new land  $q_t$  and amount against which they can borrow against each unit of land  $q_{t+1}/R$*

# FARMERS IN THE AGGREGATE

- Farmer aggregate landholding & borrowing

$$K_t = \frac{1}{u_t} [(a + q_t)K_{t-1} - RB_{t-1}]$$

$$B_t = \frac{1}{R} q_{t+1} K_t$$

- Note: higher  $q_t, q_{t+1} \rightarrow$  farmers demand *more*  $k_t$ 
  - can borrow more when  $q_{t+1}k_t$  (collateral) values higher
  - net worth higher when  $q_t$  higher

# EQUILIBRIUM RESULTS: GATHERERS

- Gatherer's demand for land.

$$G'(k'_t)/R = u_t = \underbrace{q_t - (q_{t+1}/R)}_{\text{user cost}}$$

Equalize the marginal product of land ( $G'(k'_t)$ ) with its opportunity cost ( $Rq_t - q_{t+1}$ ).

# MARKET CLEARING

- Land market resource constraint

$$mk'_t + K_t = \bar{K}$$

- Land market clearing

$$u_t = q_t - q_{t+1}/R = G' \left( \underbrace{\frac{1}{m}(\bar{K} - K_t)}_{k'} \right) / R$$

Note  $u_t$  is decreasing in  $k'_t$  (increasing in  $K_t$ ) and gatherers are not constrained, then  $R = \frac{1}{\beta'}$ .

- ASS: No bubbles in land price:  $\lim_{s \rightarrow \infty} E_t(R^{-s} q_{t+s}) = 0$

## STEADY STATE

$$u^* = (1 - 1/R)q^* = a$$

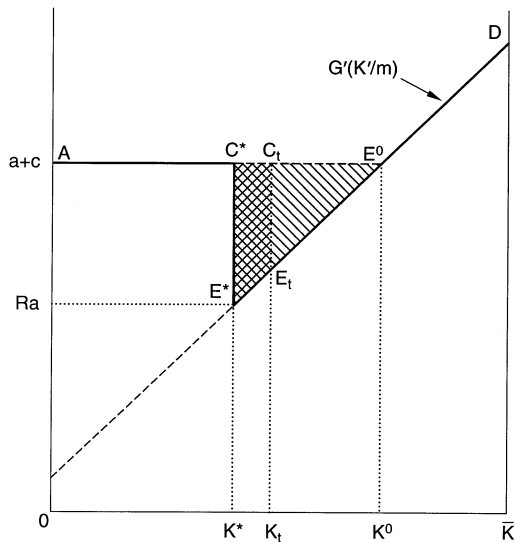

$$u^* = G' \left( \frac{1}{m}(\bar{K} - K^*) \right) / R$$

$$(R - 1)B^* = aK^*$$

Assumption 1:  $Ra = G' \left( \frac{1}{m}(\bar{K} - K^*) \right) < \frac{a}{\beta} < a + c$ .

Inefficient allocation because of collateral constraint.

## STEADY STATE

# ONE-TIME PRODUCTIVITY SHOCK

- Say  $y_{t+1} = (1 + \Delta)(a + c)k_t$
- Period of shock (period  $t$ )

$$u(K_t)K_t = (a + \Delta a)K^* + q_t K^* - \underbrace{RB^*}_{q^* K^*}$$

$$\implies u(K_t)K_t = (a + \Delta a + q_t - q^*)K^*$$

- Subsequent periods (periods  $t + s$ ,  $s = 1, 2, \dots$ )

$$u(K_{t+s})K_{t+s} = aK_{t+s-1} + \underbrace{q_{t+s}K_{t+s-1} - RB_{t+s-1}}_{=0}$$

# ONE-TIME PRODUCTIVITY SHOCK

- Log-linearize around steady state
- Define for variable  $X_t$  the proportional change from steady state

$$\hat{X}_t = \frac{X_t - X^*}{X^*}$$

- Period of shock (period  $t$ )

$$(1 + 1/\eta)\hat{K}_t = \Delta + \frac{R}{R-1}\hat{q}_t$$

- Subsequent periods (periods  $t + s$ ,  $s = 1, 2, \dots$ )

$$(1 + 1/\eta)\hat{K}_{t+s} = \hat{K}_{t+s-1}$$

where  $\eta$  denotes elasticity of land supply of gatherers to user cost

# RESPONSE OF LAND PRICE & LAND HOLDINGS

- Land price response

$$\hat{q}_t = \frac{1}{\eta} \Delta$$

- Overall land holding response

$$\hat{K}_t = \underbrace{\frac{1}{1 + \frac{1}{\eta}} \left( 1 + \frac{R}{R-1} \frac{1}{\eta} \right)}_{>1} \Delta$$

# RESPONSE OF LAND PRICE & LAND HOLDINGS

- Land price response

$$\hat{q}_t = \frac{1}{\eta} \Delta$$

- Overall land holding response

$$\hat{K}_t = \underbrace{\frac{1}{1 + \frac{1}{\eta}} \left( 1 + \frac{R}{R-1} \frac{1}{\eta} \right)}_{>1} \Delta$$

- Say  $\eta = 1$ ,  $R = 1.05$

$$\hat{K}_t \approx 11\Delta$$

# STATIC RESPONSE OF LAND PRICE & LAND HOLDINGS

- Land price response

$$\hat{q}_t|_{q_{t+1}=q^*} = \frac{1}{\eta} \underbrace{\frac{R-1}{R}}_{<1} \Delta$$

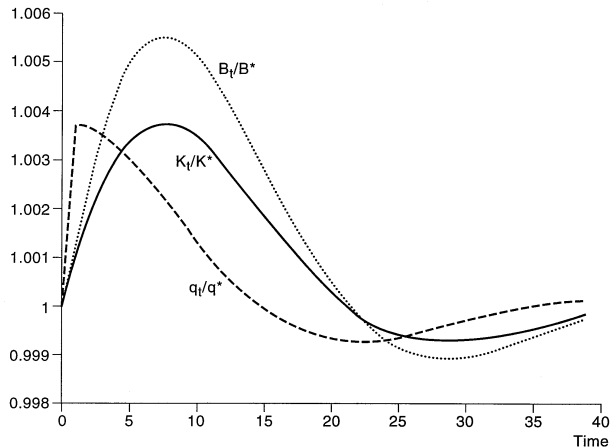

- Overall land holding response

$$\hat{K}_t|_{q_{t+1}=q^*} = \Delta$$

# RESPONSE OF OUTPUT & PRODUCTIVITY

$$\hat{Y}_{t+s} = \underbrace{\frac{a + c - Ra}{a + c}}_{\text{Productivity diff.}} \underbrace{\frac{(a + c)K^*}{Y^*}}_{\text{Farmers' share}} \hat{K}_{t+s-1}$$

## RESPONSE TO SHOCK

# NET WORTH SHOCK

- One time reduction in debt obligations
- Increases net worth
- Farmer increases leverage, production
- Another view of Bernanke-Paulson policies?

# WRAPPING UP

- Firms' productive capital also used as collateral
- Amplification and persistency of real shocks through lower collateral value of capital
- Real effects of lower asset values and financial frictions.

## CRITIQUES/COMMENTS

- Kocherlakota (QR, 2000): Quantitative importance likely to be small if land & capital share less than 0.4
- Andres Arias (WP, 2005): Calibrated RBC model with KM credit constraints deliver small amplification effects
- Brunnermeier and Sannikov (2014): Non-linearities during crises.
- *Real effects of housing/stock bubbles*

# THE CONCEPTUAL IDEA

- **Main Paper: Bernanke and Gertler (AER, 1989).**
- Costly state verification in a Real Business Cycle model.
- **Debt-Deflation meets Real Business Cycle.**
- Main idea.
  - The borrowers' net worth determines both their risk of default and agency problems (the intermediation cost).
  - Net worth is procyclical.
  - In recessions the costs of intermediation increase, reduce the net return of investment and depress investment, magnifying the recession.

# ENVIRONMENT

- Risk neutral  $E$  and  $L$ .
- $E$  has net worth  $n$ .
- $E$ 's technology:
  - $i$  units of  $c$  good  $\rightarrow \omega i$  units of  $k$  good
  - $\omega$  is iid over time and investors, st,  $\int_0^\infty \omega d\Phi(\omega) = 1$ .
  - We denote by  $q$  the price of the  $k$  good in terms of the  $c$  good.
- A fancy costly state verification
  - $\omega$  is private information to  $E$ .  $L$  has to pay  $\mu i$  to learn  $\omega$

# CONTRACTING PROBLEM

- E borrows  $i - n$  in  $c$  goods and repays  $(1 + r^k)(i - n)$  in  $k$  goods.
- E defaults iff  $\omega \leq \bar{\omega} \equiv (1 + r^k) \frac{i - n}{i}$ .
- Then

$$r^k = \frac{\bar{\omega} i}{i - n} - 1$$

## EXPECTED INCOME FOR $E$ AND $L$

- E's expected income (in terms of  $c$  goods)

$$\begin{aligned}
 & q \left[ \int_{\bar{\omega}}^{\infty} \omega i d\Phi(\omega) - (1 - \Phi(\bar{\omega}))(1 + r^k)(i - n) \right] \\
 = & \underbrace{qi \left[ \int_{\bar{\omega}}^{\infty} \omega i d\Phi(\omega) - (1 - \Phi(\bar{\omega}))\bar{\omega} \right]}_{f(\bar{\omega})}
 \end{aligned}$$

- L's expected income (in terms of  $c$  goods)

$$\begin{aligned}
 & q \left[ \int_0^{\bar{\omega}} \omega i d\Phi(\omega) + (1 - \Phi(\bar{\omega}))(1 + r^k)(i - n) - \Phi(\bar{\omega})\mu i \right] \\
 = & \underbrace{qi \left[ \int_0^{\bar{\omega}} \omega i d\Phi(\omega) + (1 - \Phi(\bar{\omega}))\bar{\omega} - \Phi(\bar{\omega})\mu \right]}_{g(\bar{\omega})}
 \end{aligned}$$

# OPTIMAL CONTRACT

- The optimal contract specifies

$$\max_{i, \bar{\omega}} q i f(\bar{\omega}) \quad st \quad q i g(\bar{\omega}) \geq i - n$$

- From the participation constraint,  $i$  is increasing in  $q$  and  $n$

$$i = \frac{1}{1 - qg(\bar{\omega})} n$$

- The maximization becomes

$$\max_{\bar{\omega}} q \frac{n}{1 - qg(\bar{\omega})} f(\bar{\omega})$$

# OPTIMAL CONTRACT

- FOC

$$g(\bar{\omega}) - g'(\bar{\omega}) \frac{f(\bar{\omega})}{f'(\bar{\omega})} = \frac{1}{q}$$

where

$$f(\bar{\omega}) + g(\bar{\omega}) = 1 - \mu\Phi(\bar{\omega})$$

$$f'(\bar{\omega}) + g'(\bar{\omega}) = -\mu\phi(\bar{\omega})$$

- Then, implicit function  $\bar{\omega}(q)$  increasing in  $q$ ,

$$1 - \mu\Phi(\bar{\omega}) + \phi(\bar{\omega})\mu \frac{f(\bar{\omega})}{f'(\bar{\omega})} = \frac{1}{q}$$

# THE QUANTITATIVE APPLICATION

- **Main Paper: Carlstrom and Fuerst (AER, 1997).**
- Financial frictions provide a propagation mechanism....is this large quantitatively?

# GENERAL EQUILIBRIUM MODEL

- Players
  - Two types of consumers
    - HHs: Households (risk averse)
    - E: Entrepreneur (risk neutral)
  - MF: Mutual Fund channels funds from HHs to E.

# GENERAL EQUILIBRIUM MODEL

- Sequence of Events
  - $\theta_t$ : Aggregate productivity shocks
  - Firms produce  $c$  goods:  $Y_t = \theta_t F(K_t, L_t^{HH}, L_t^E)$
  - HHs buy  $c$  goods and order new  $k$  goods from the MF at a price  $q_t$
  - MF finances loans to E (with the technology we discussed).
  - iid shocks to E (in  $\omega$ ).
  - CSV contract.
  - Production of  $k$  goods.
  - Solvent E sell capital to MF and purchase  $c$  goods.
- Production is linear and net worth can just be aggregated in an aggregated net worth.

# GENERAL EQUILIBRIUM MODEL

- This is calibrated with the following exercises.
- Shift of 0.1% of SS capital from HH to E.
  - This implies an increase in net worth of 13%.
  - $\uparrow I = 5.5\%$  and  $\downarrow q$ .
  - $\downarrow C^{HH} = 0.8\%$ ,  $\uparrow L^{HH} = 2.2\%$  and  $\uparrow Y = 1.4\%$
- A positive productivity shock on  $\theta$ .
  - Increase in the demand for  $k$  goods but slow response on  $n$ .
  - Hump shaped increase in  $Y$ .

# MOTIVATION

- **Main paper: Gorton and Ordonez (AER 14)**
- Information is at the heart of financial intermediation.
- Transparency is at the heart of new proposed regulation.
- How information production shapes business cycles?
- Should policies induce information production?
- We show information dynamics can account for fragility, magnification, persistence and asymmetry of cycles.

## PEEKING AT THE RESULTS

- In a world of collateralized short-term debt, symmetric ignorance about the quality of collateral may be efficient.
  - Firms with bad collateral get loans that they otherwise would not. "Ignorance Credit Boom".
- but fragile to small shocks that induce asymmetric information.
  - Firms with good collateral do not get loans that they otherwise would. "Collateral Crises".
- Endogenous tail events. Larger booms lead to larger crises.

# SETTING

- Single Period. Mass 1 of risk-neutral firms and households.

$$K' = \begin{cases} A \min\{K, L^*\} & \text{with prob. } q \\ 0 & \text{with prob. } (1 - q) \end{cases}$$

$qA > 1$ . Optimal scale  $K^* = L^*$

- Households:  $\bar{K} > K^*$ .
- Firms:  $L^*$  and a unit of land.

# SETTING

- Single Period. Mass 1 of risk-neutral firms and households.

$$K' = \begin{cases} A \min\{K, L^*\} & \text{with prob. } q \\ 0 & \text{with prob. } (1 - q) \end{cases}$$

$qA > 1$ . Optimal scale  $K^* = L^*$

- Households:  $\bar{K} > K^*$ .
- Firms:  $L^*$  and a unit of land.

$$\begin{cases} C > K^* & \text{with prob. } p \\ 0 & \text{with prob. } (1 - p) \end{cases}$$

Only households can privately learn the truth at a cost  $\gamma$ .

# INDUCE INFORMATION

- Symmetric Information.
- Lenders break even and debt is risk free

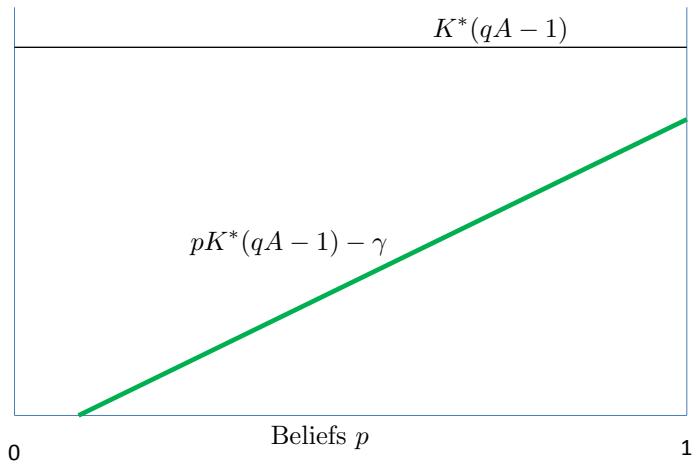

$$p(qR_{IS} + (1 - q)xC) = \gamma + pK \quad \text{and} \quad R_{IS} = xC$$

Then

$$x = \frac{pK + \gamma}{pC} \leq 1$$

# INDUCE INFORMATION

$$E(\text{Profits}) = E(K')$$

# DO NOT INDUCE INFORMATION

- Symmetric Ignorance.
- Lenders break even and debt is risk free

$$qR_{II} + (1 - q)pxC = K \quad \text{and} \quad R_{II} = pxC$$

$$\text{Then } x = \frac{K}{pC} \leq 1$$

# DO NOT INDUCE INFORMATION

- Symmetric Ignorance.
- Lenders break even and debt is risk free

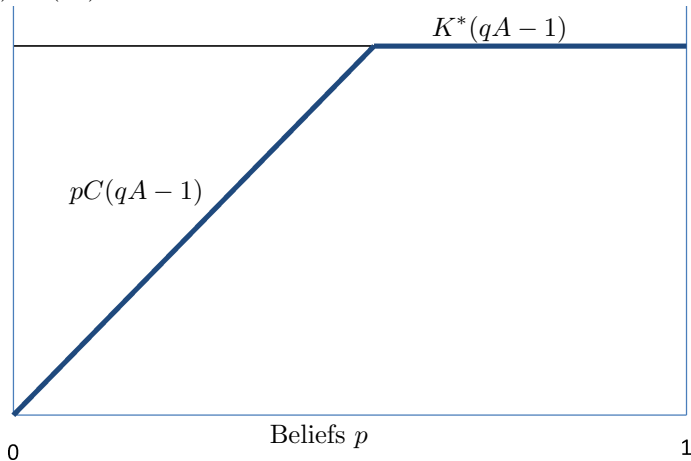

$$qR_{II} + (1 - q)pxC = K \quad \text{and} \quad R_{II} = pxC$$

$$\text{Then } x = \frac{K}{pC} \leq 1$$

- Subject to loans not triggering information acquisition.

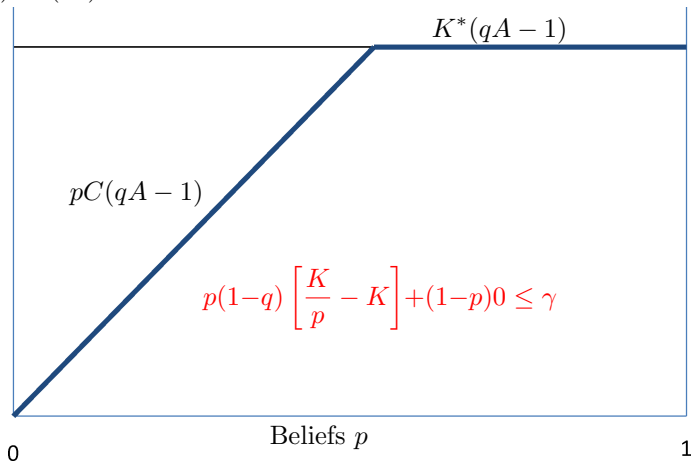

## DO NOT INDUCE INFORMATION

$$E(\text{Profits}) = E(K')$$

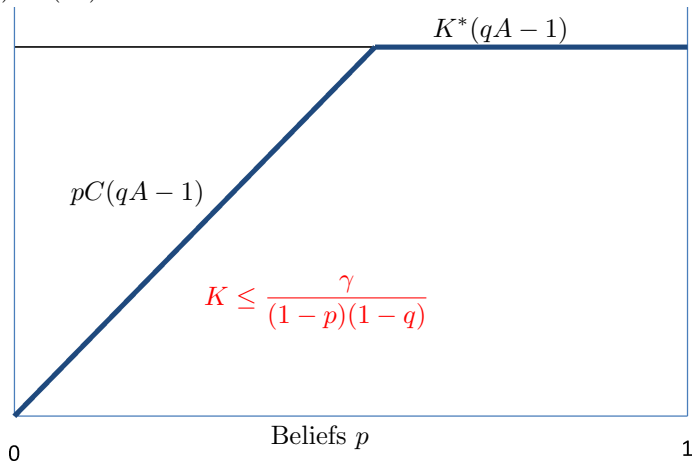

## DO NOT INDUCE INFORMATION

$$E(\text{Profits}) = E(K')$$

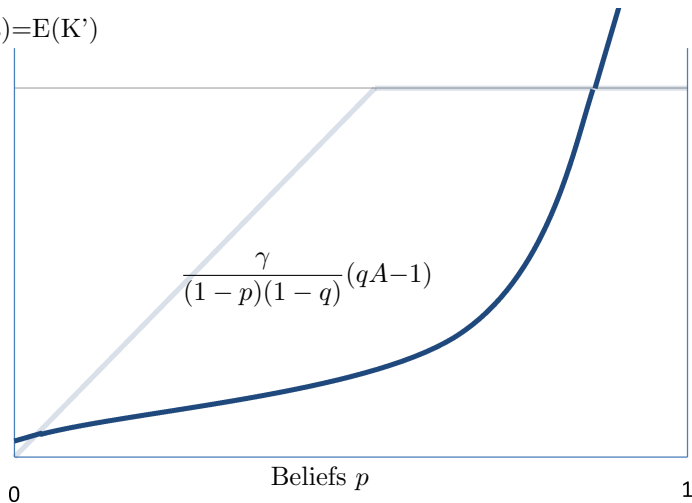

## DO NOT INDUCE INFORMATION

$$E(\text{Profits}) = E(K')$$

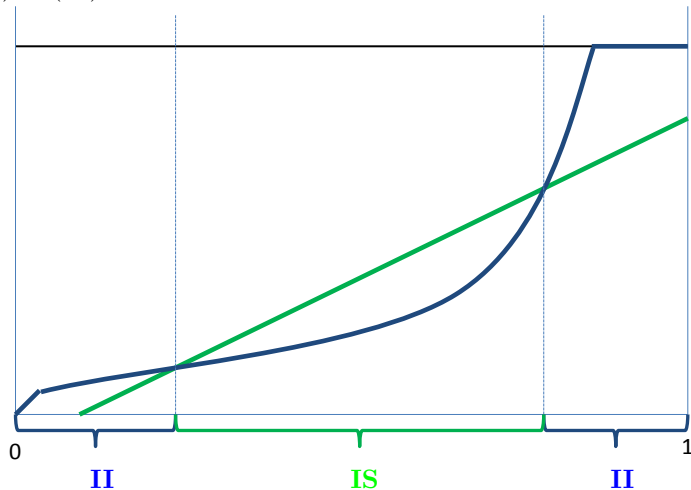

## DO NOT INDUCE INFORMATION

$$E(\text{Profits}) = E(K')$$

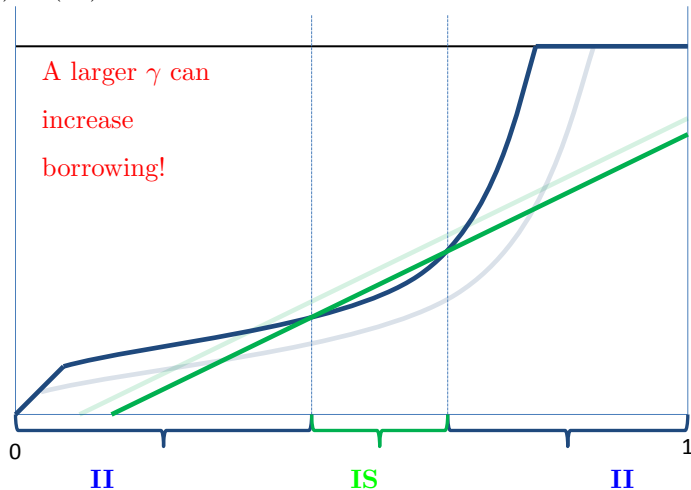

## OPTIMAL INFORMATION

$$E(\text{Profits}) = E(K')$$

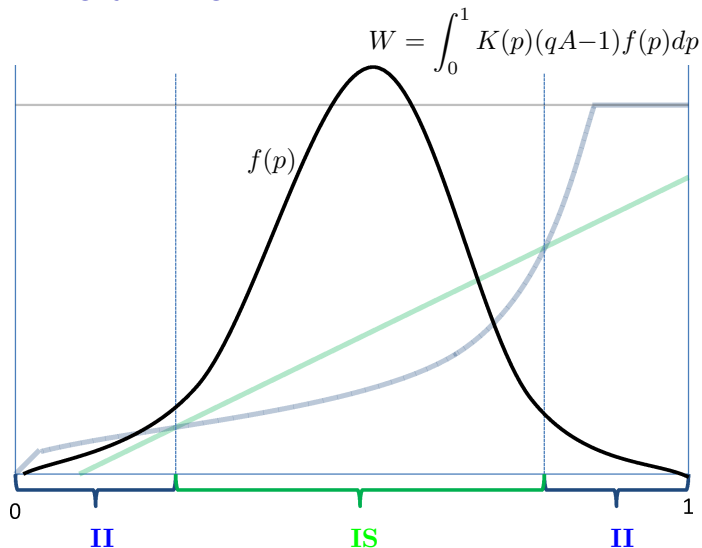

## OPTIMAL INFORMATION

$$E(\text{Profits}) = E(K')$$

## OPTIMAL INFORMATION

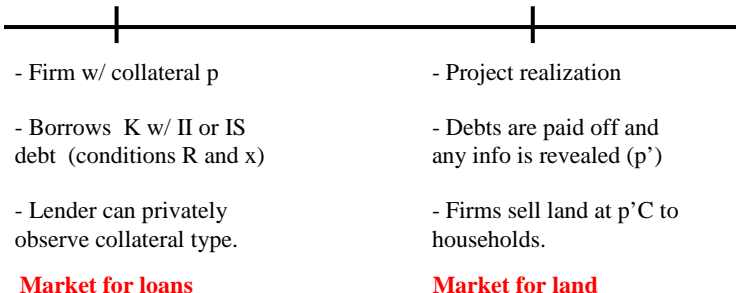

# SETTING DYNAMICS

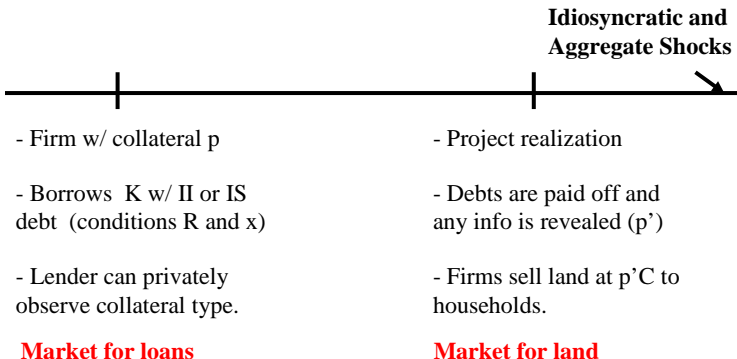

How this distribution of beliefs evolves over time?

- Dynamic extension.
  - OG: "young" households, "old" firms.
  - Land is storable,  $K$  is not.
  - Land is transferred across generations.
  - We assume away bubbles and multiplicity.
  - There are no fire sales.
  - Price is  $pC$  (i.e., single match and buyers' negotiation power).

## TIMING

## TIMING

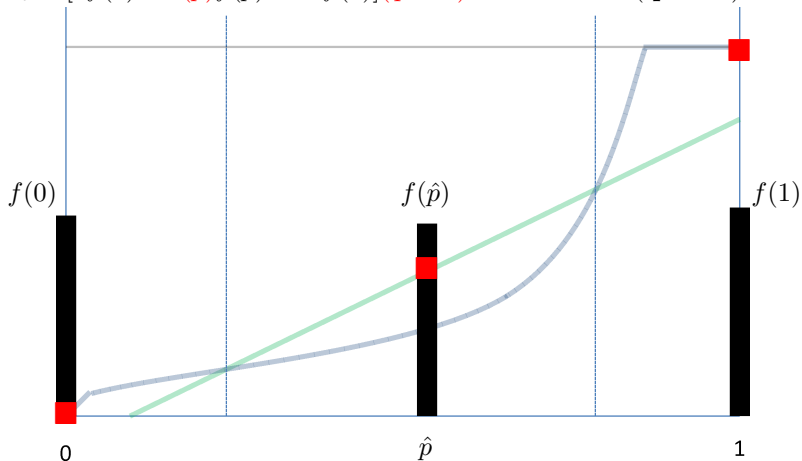

# EVOLUTION OF COLLATERAL TYPES

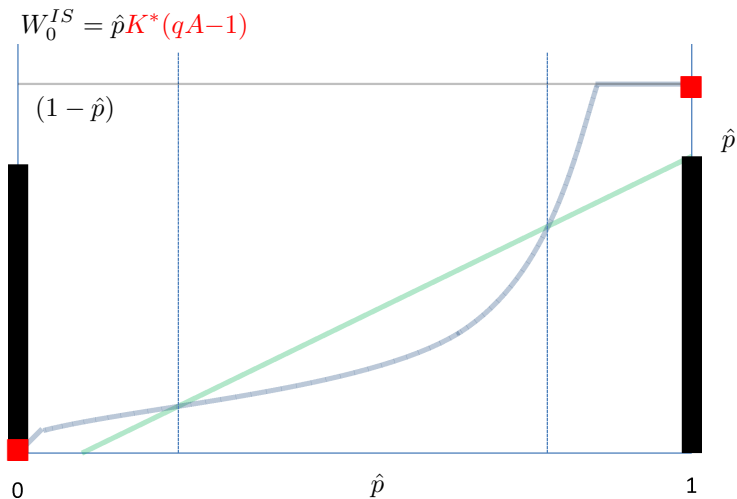

- Important assumption: Mean reversion of collateral.
- Simplifying assumptions
  - $\hat{p}$ : Fraction of good land.
  - Idiosyncratic shocks
    - Occur with probability  $(1 - \lambda)$
    - Land becomes good with probability  $\hat{p}$ .
    - The shock is observable, the realization is not.

## SIMPLER AGGREGATION

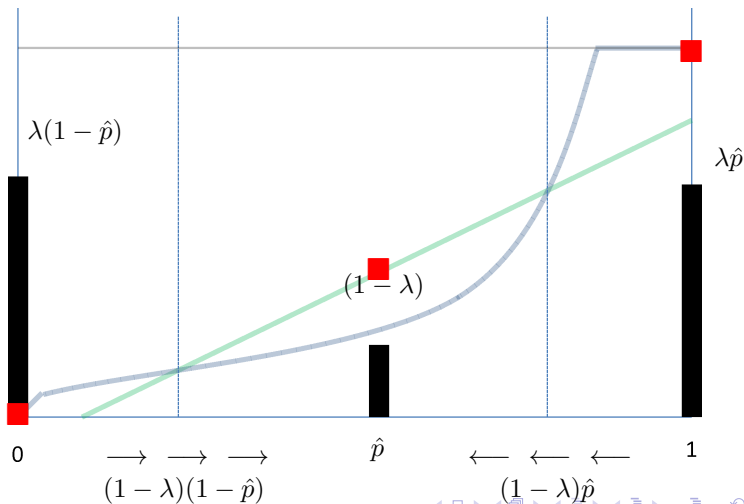

$$W_t = [0f(0) + K(\hat{p})f(\hat{p}) + K^*f(1)](qA - 1) < W^* = K^*(qA - 1)$$

# INFORMATION SENSITIVE DYNAMICS

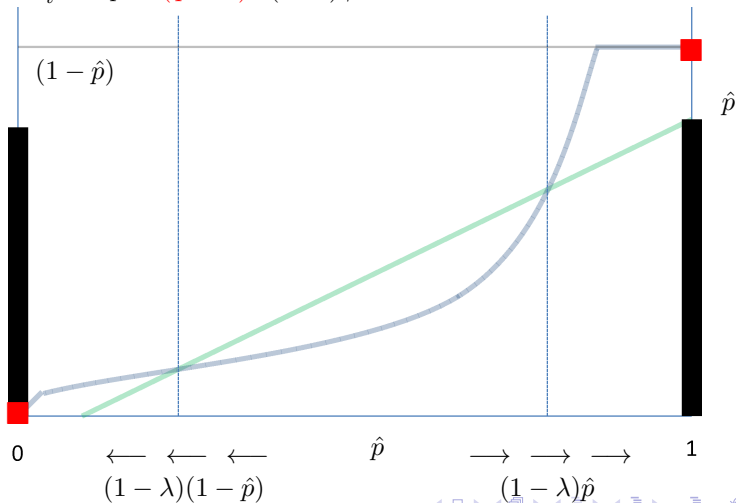

# INFORMATION SENSITIVE DYNAMICS

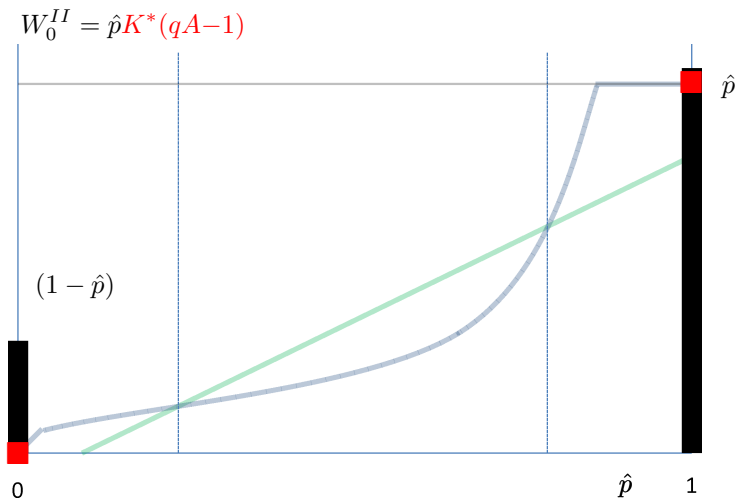

# INFORMATION SENSITIVE DYNAMICS

$$W_t^{IS} = \hat{p}K^*(qA-1) - (1-\lambda)\gamma < \mathbf{W}^*$$

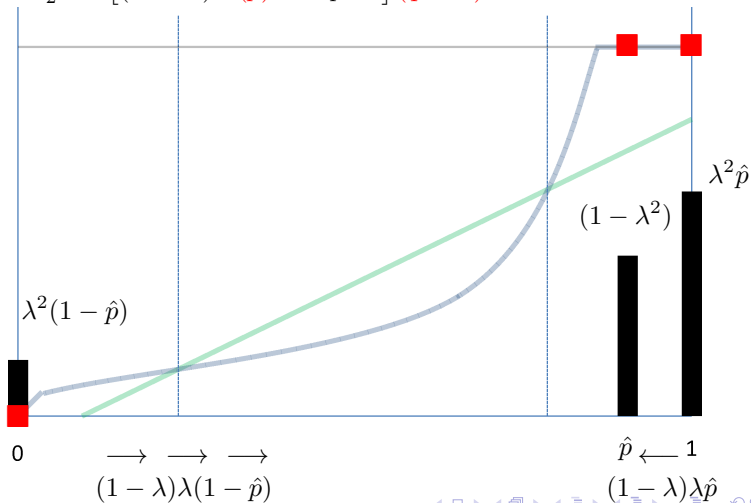

# INFORMATION INSENSITIVE DYNAMICS

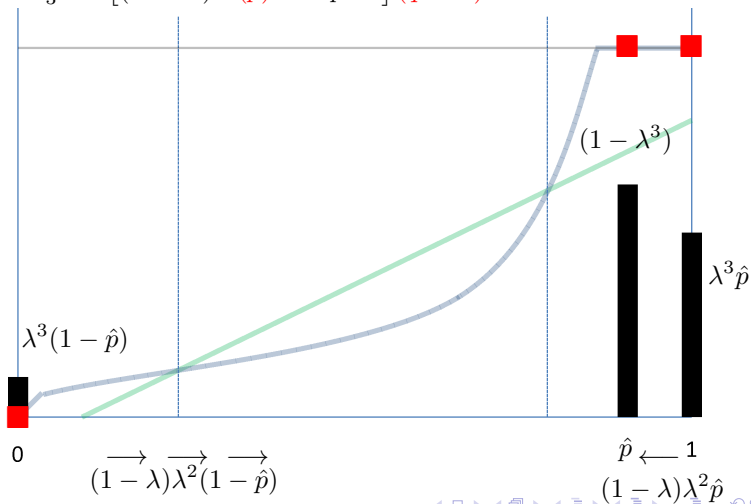

# INFORMATION INSENSITIVE DYNAMICS

$$W_2^{II} = [(1 - \lambda^2)K(\hat{p}) + \lambda^2\hat{p}K^*] (qA - 1)$$

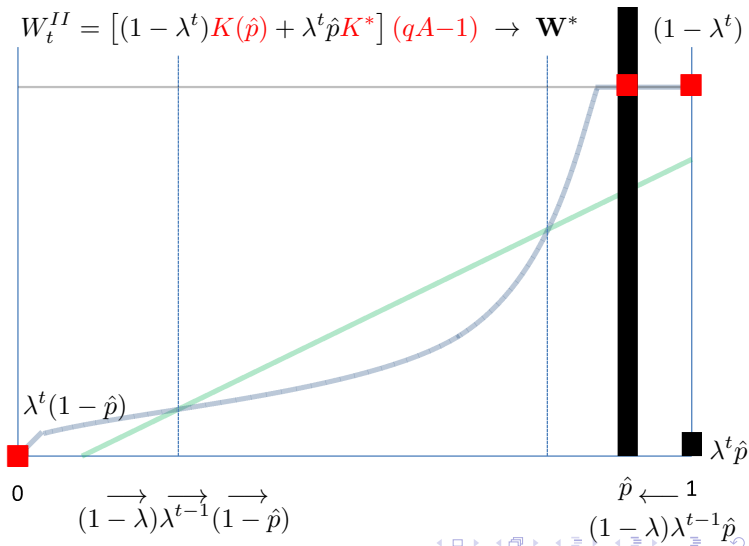

## INFORMATION INSENSITIVE DYNAMICS

$$W_3^{II} = [(1 - \lambda^3)K(\hat{p}) + \lambda^3\hat{p}K^*] (qA - 1)$$

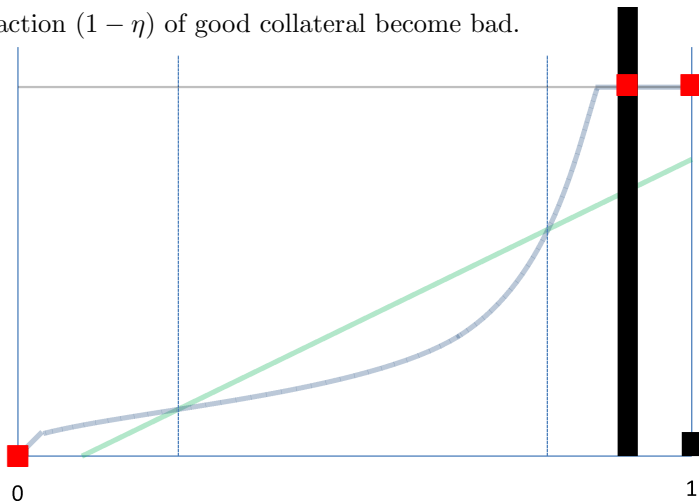

## INFORMATION INSENSITIVE DYNAMICS

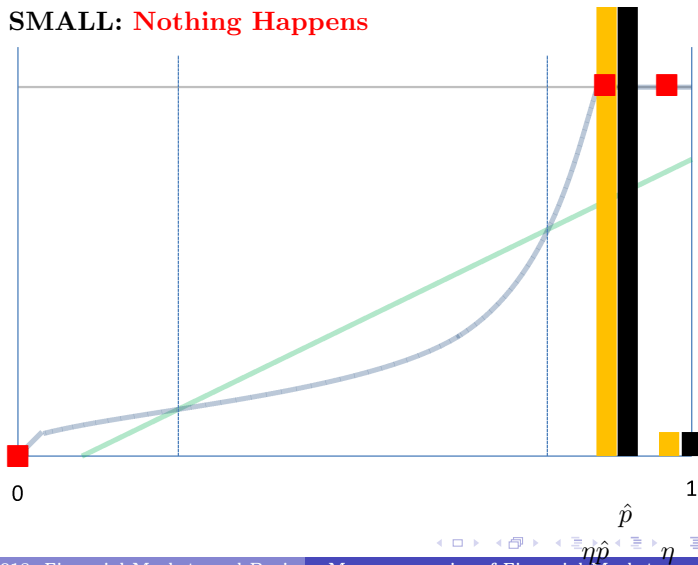

# NEGATIVE AGGREGATE SHOCKS

A fraction  $(1 - \eta)$  of good collateral become bad.

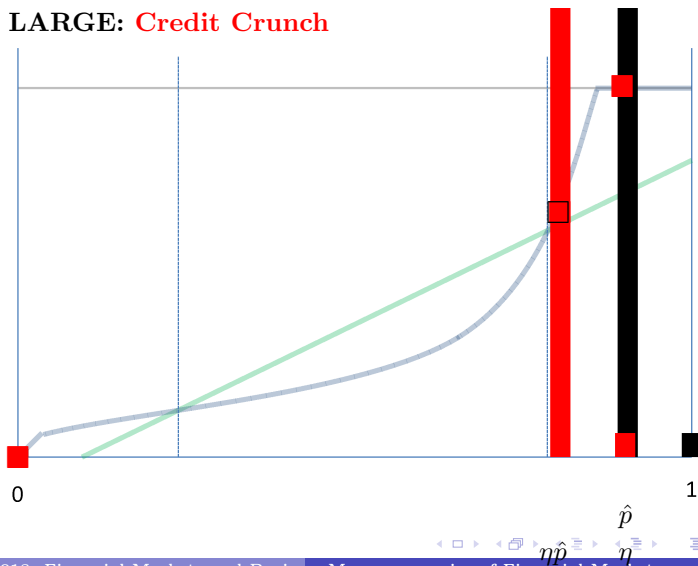

# NEGATIVE AGGREGATE SHOCKS

**SMALL:** Nothing Happens

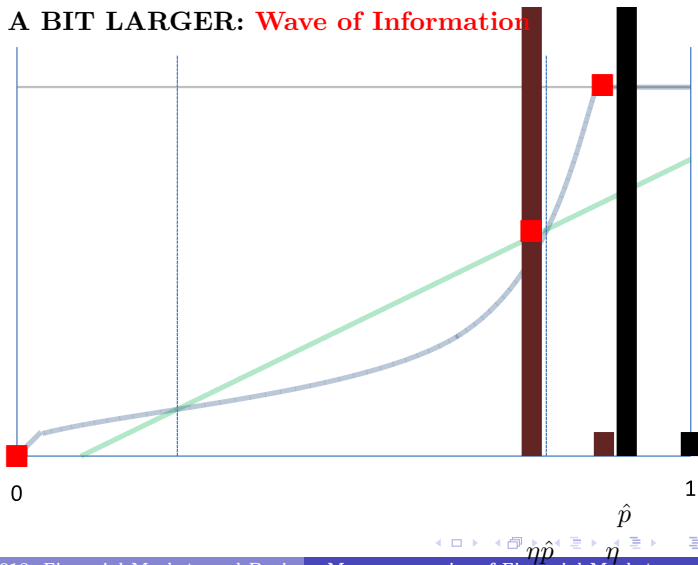

# NEGATIVE AGGREGATE SHOCKS

**LARGE: Credit Crunch**

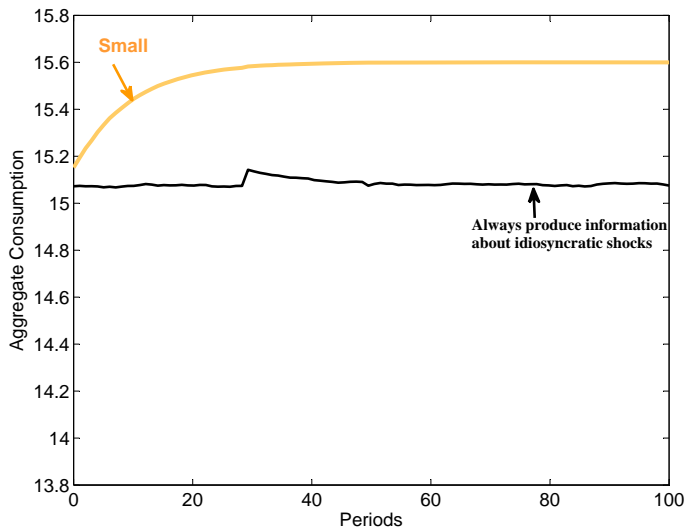

# NEGATIVE AGGREGATE SHOCKS

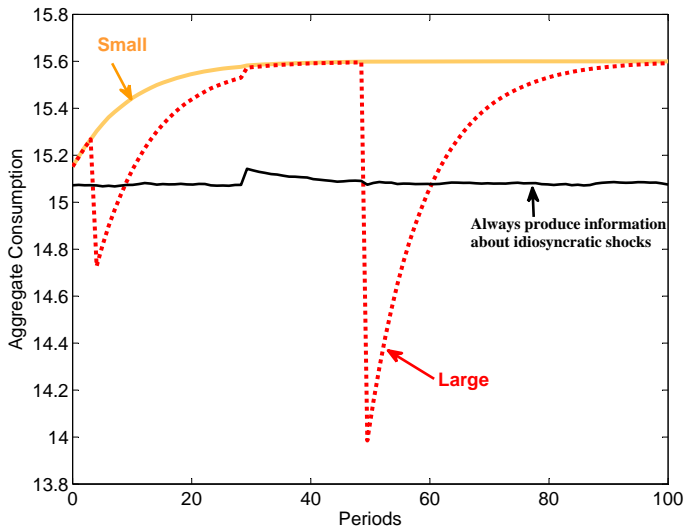

A BIT LARGER: Wave of Information

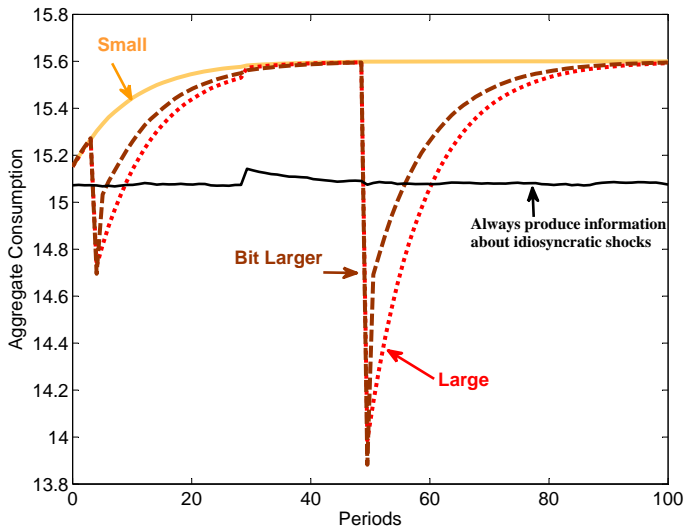

## NUMERICAL EXAMPLE

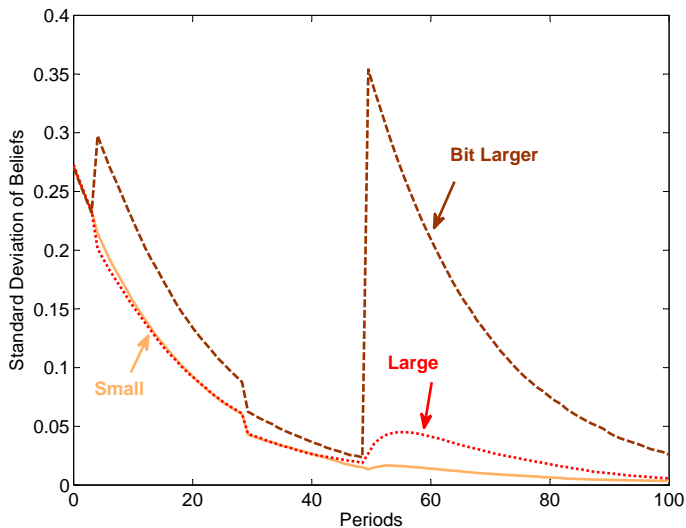

# NUMERICAL EXAMPLE

# NUMERICAL EXAMPLE

## NUMERICAL EXAMPLE

# A PLANNER

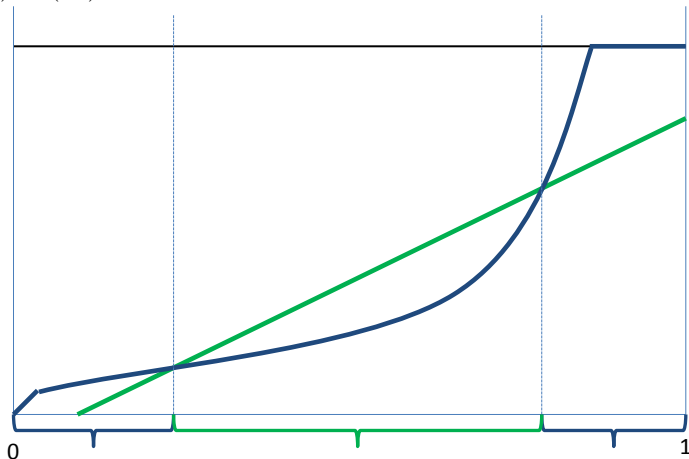

- Assume a planner that maximizes the discounted utility of cohorts

$$U_t = E_t \sum_{\tau=t}^{\infty} \beta^{\tau-t} W_{\tau}.$$

- Optimal range of information production is wider.
- The planner can implement the optimum by subsidizing a fraction  $\beta\lambda$  of the information cost  $\gamma$ .

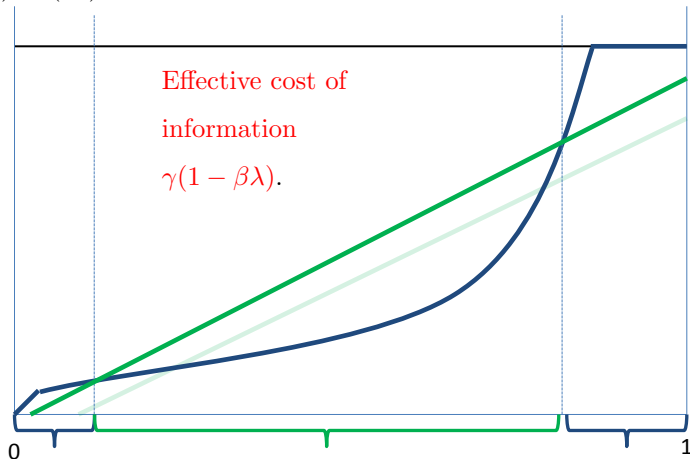

## A PLANNER: CUTOFFS

$$E(\text{Profits}) = E(K')$$

# A PLANNER: CUTOFFS

$$E(\text{Profits}) = E(K')$$

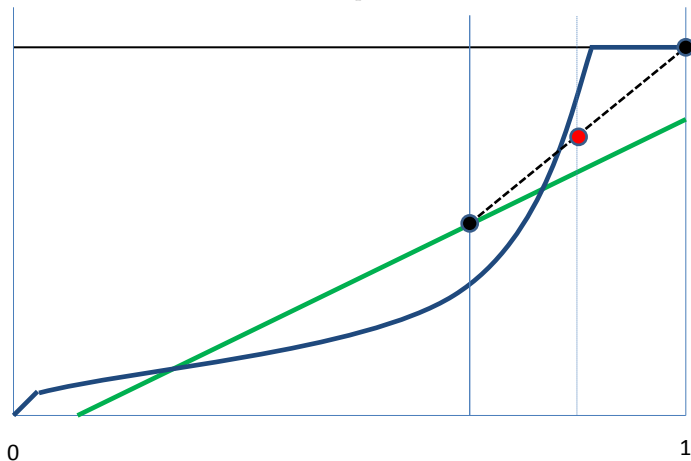

# EXTENSIONS

- Endogenous complex securities.
- Real Shocks.
- Two Sided Information Production.
- Crises without shocks.

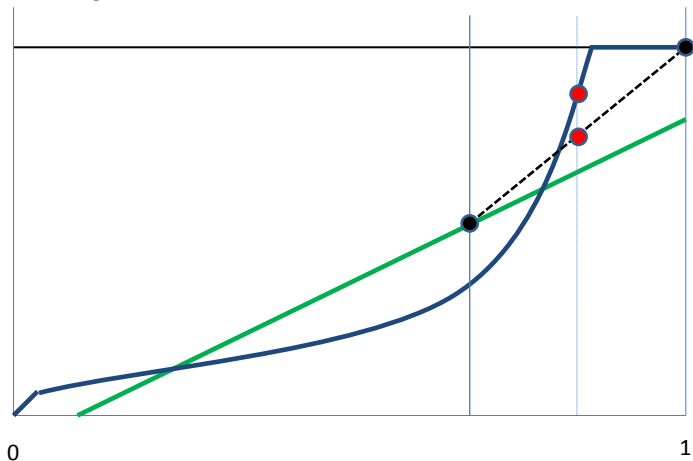

# ENDOGENOUS SECURITY STRUCTURE

Two securities with different  $p$

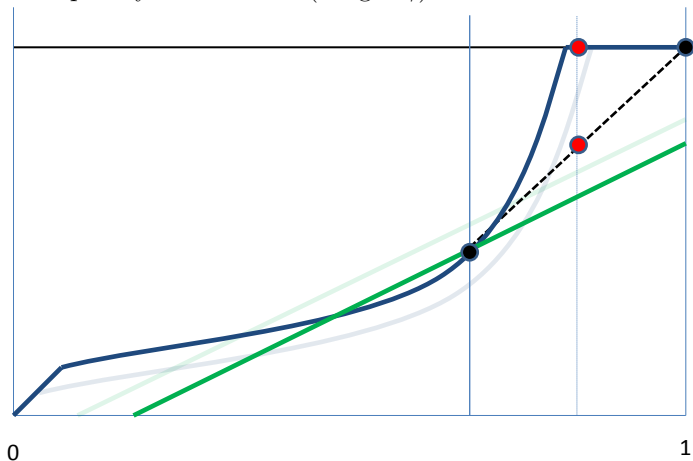

## ENDOGENOUS SECURITY STRUCTURE

Pooling Collateral

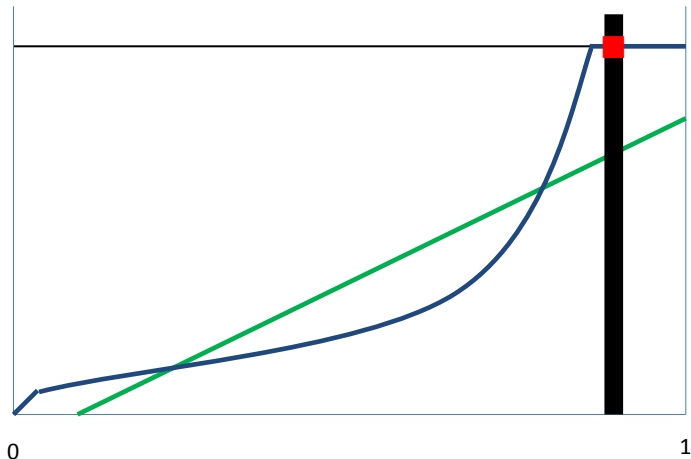

# ENDOGENOUS SECURITY STRUCTURE

Complexity of Securities (Larger  $\gamma$ )

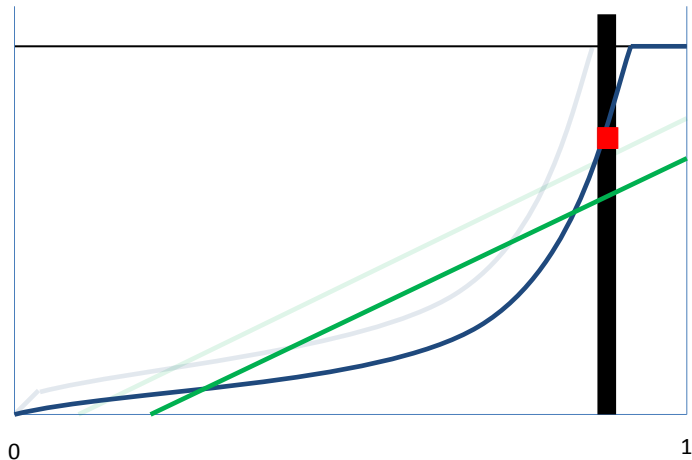

# A REAL SOURCE OF A CREDIT CRUNCH

A reduction in the success probability  $q$  can lead to a credit crunch.

# A REAL SOURCE OF A CREDIT CRUNCH

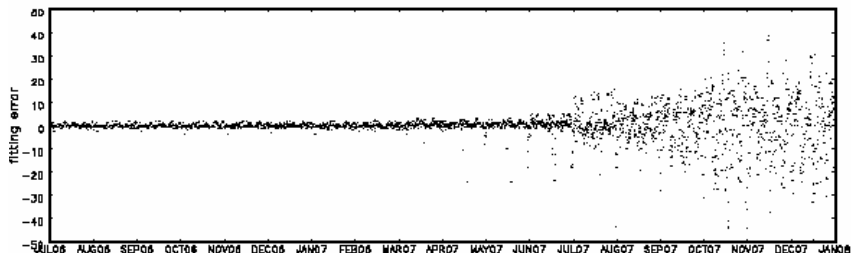

A reduction in the success probability  $q$  can lead to a credit crunch.

## SUGGESTIVE EVIDENCE INFORMATION PRODUCTION

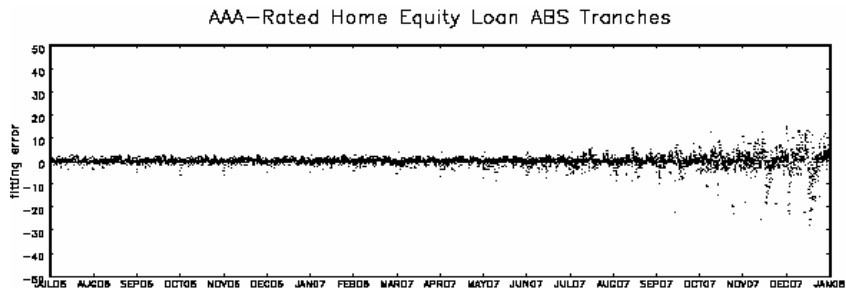

Perraudin and Wu (2008)

AA-Rated Home Equity Loan ABS Tranches

## SUGGESTIVE EVIDENCE INFORMATION PRODUCTION

Perraudin and Wu (2008)

## FINAL REMARKS

- Symmetric ignorance may be socially desirable, but it is vulnerable to a sudden loss of confidence in its symmetry.
- Macroeconomic implications:
  - Larger “ignorance credit booms” lead to larger crises.
  - The planner may not want to eliminate fragility.
  - Dispersion of beliefs (and of credit and production) is endogenous. We are testing this implication of the mechanism empirically (Kyriakos, Gorton and Ordóñez, 18?).
